1 Introduction

1.1 Overview

This Reference Architecture is focussed on OpenStack as the Virtualised Infrastructure Manager (VIM) chosen based on the criteria laid out in the Reference Model 0. OpenStack **Error! Reference source not found.** has the advantage of being a mature and widely accepted open-source technology; a strong ecosystem of vendors that support it, the OpenInfra Foundation for managing the community, and, most importantly, it is widely deployed by the global operator community for both internal infrastructure and external facing products and services. This means that the operators have existing staff with the right skill sets to support a Cloud Infrastructure (NFVI 0) deployment into development, test, and production. Another reason to choose OpenStack is that it has a large active community of vendors and operators, which means that any code or component changes needed to support the Common Telco Cloud Infrastructure requirements can be managed through the existing project communities' processes to add and validate the required features through well-established mechanisms.

1.1.1 Vision

The OpenStack-based Reference Architecture (RA) will host NFV workloads, primarily VNFs, of interest to the Anuket community. The Reference Architecture document can be used by operators to deploy Anuket conformant infrastructure; hereafter, "conformant" denotes that the resource can satisfy tests conducted to verify conformance with this reference architecture.

1.2 Use Cases

Several NFV use cases are documented in OpenStack. For more examples and details refer to the OpenStack docs **Error! Reference source not found.** Examples include:

- **Overlay networks:** The overlay functionality design includes OpenStack Networking in Open vSwitch **Error! Reference source not found.** GRE tunnel mode. In this case, the layer-3 external routers pair with VRRP, and switches pair with an implementation of MLAG to ensure that you do not lose connectivity with the upstream routing infrastructure.
- **Performance tuning:** Network level tuning for this workload is minimal. Quality of Service (QoS) applies to these workloads for a middle ground Class Selector depending on existing policies. It is higher than a best effort queue but lower than an Expedited Forwarding or Assured Forwarding queue. Since this type of application generates larger packets with longer-lived connections, you can optimize bandwidth utilization for long duration TCP. Normal bandwidth planning applies here with regards to benchmarking a session's usage multiplied by the expected number of concurrent sessions with overhead.
- **Network functions:** Network functions is a broad category of workloads that support the exchange of information (data, voice, multi-media) over a system's network. Some of these workloads tend to consist of a large number of small-sized packets that are short lived, such as DNS queries or SNMP traps. These messages need to arrive quickly and, thus, do not handle packet loss. Network function workloads have requirements that may affect configurations including at the hypervisor level. For an

application that generates 10 TCP sessions per user with an average bandwidth of 512 kilobytes per second per flow and expected user count of ten thousand (10,000) concurrent users, the expected bandwidth plan is approximately 4.88 gigabits per second. The supporting network for this type of configuration needs to have a low latency and evenly distributed load across the topology. These types of workload benefit from having services local to the consumers of the service. Thus, use a multi-site approach, as well as, deploying many copies of the application to handle the load as close as possible to consumers. Since these applications function independently, they do not warrant running overlays to interconnect tenant networks. Overlays also have the drawback of performing poorly with rapid flow setup and may incur too much overhead with large quantities of small packets and therefore we do not recommend them. QoS is desirable for some workloads to ensure delivery. DNS has a major impact on the load times of other services and needs to be reliable and provide rapid responses. Configure rules in upstream devices to apply a higher-Class Selector to DNS to ensure faster delivery or a better spot in queuing algorithms.

1.4 OpenStack-based Reference Release

This Reference Architecture document conforms to the OpenStack Train **Error! Reference source not found.** release. While many features and capabilities are conformant with many OpenStack releases, this document will refer to features, capabilities and APIs that are part of the OpenStack Train release. For ease, this Reference Architecture document version can be referred to as "RA-1 OSTK Train."

1.5 Principles

OpenStack Reference Architecture must obey to the following set of principles:

1. Requirements Principles (GSMA PRD NG126 Annex A.2 0)
2. Architectural Principles (GSMA PRD NG126 Annex A.3 0)

1.5.1 OpenStack specific principles

OpenStack considers the following Four Opens essential for success:

1. Open Source
2. Open Design
3. Open Development
4. Open Community

This OpenStack Reference Architecture is organised around the three major Cloud Infrastructure resource types as core services of compute, storage and networking, and a set of shared services of identity management, image management, graphical user interface, orchestration engine, etc.

1.6 Document Organisation

Section 2 defines the Reference Architecture requirements and, when appropriate, provides references to where these requirements are addressed in this document. The intent of this document is to address all of the mandatory ("must") requirements and the most useful of the other optional ("should") requirements. Section 3 and 4 cover the Cloud Infrastructure resources and the core OpenStack services, while the APIs are covered in Section 5.

Section 6 covers the implementation and enforcement of security capabilities and controls. Life Cycle Management of the Cloud Infrastructure and VIM are covered in Section 7 with stress on Logging, Monitoring and Analytics (LMA), configuration management and some other operational items. Please note that Section 7 is not a replacement for the implementation, configuration and operational documentation that accompanies the different OpenStack distributions. Section 8 identifies certain Gaps that currently exist and plans on how to address them. For example, Service Function Chaining support needs to be addressed to realise the full potential and value of SDN and NFV.

1.7 Terminology

General OpenStack terminology definitions can be found in the Glossary **Error! Reference source not found.** while specific terms relating to this reference architecture are listed below.

Abstraction: Process of removing concrete, fine-grained or lower-level details or attributes or common properties in the study of systems to focus attention on topics of greater importance or general concepts. It can be the result of decoupling.

Cloud Infrastructure: A generic term covering **NFVI**, **IaaS** and **CaaS** capabilities - essentially the infrastructure on which a **Workload** can be executed.

Note: **NFVI**, **IaaS** and **CaaS** layers can be built on top of each other. In case of CaaS some cloud infrastructure features (e.g.: HW management or multitenancy) are implemented by using an underlying **IaaS** layer.

Cloud Infrastructure Hardware Configuration: a set of settings (Key: Value) that are applied/mapped to **Cloud Infrastructure** HW deployment.

Cloud Infrastructure Hardware Profile: defines the behaviour, capabilities, configuration, and metrics provided by a cloud infrastructure hardware layer resources available for the workloads.

Host Profile: is another term for a Cloud Infrastructure Hardware Profile.

Cloud Infrastructure Profile: The combination of the Cloud Infrastructure Software Profile and the Cloud Infrastructure Hardware Profile that defines the capabilities and configuration of the Cloud Infrastructure resources available for the workloads.

Cloud Infrastructure Software Configuration: a set of settings (Key: Value) that are applied/mapped to **cloud infrastructure** SW deployment.

Cloud Infrastructure Software Profile: defines the behaviour, capabilities and metrics provided by a Cloud Infrastructure Software Layer on resources available for the workloads.

Cloud Native Network Function (CNF): A cloud native network function (CNF) is a cloud native application that implements network functionality. A CNF consists of one or more microservices. All layers of a CNF are developed using Cloud Native Principles including immutable infrastructure, declarative APIs, and a “repeatable deployment process”.

Note: This definition is derived from the Cloud Native Thinking for Telecommunications Whitepaper **Error! Reference source not found.**, which also includes further detail and examples.

Compute flavour: defines the sizing of the virtualised resources (compute, memory, and storage) required to run a workload.

Note: used to define the configuration/capacity limit of a virtualised container.

Compute Node: An abstract definition of a server.

Note: A compute node can refer to a set of hardware and software that support the VMs or Containers running on it.

Container: A lightweight and portable executable image that contains software and all of its dependencies.

Note: OCI defines **Container** as "An environment for executing processes with configurable isolation and resource limitations. For example, namespaces, resource limits, and mounts are all part of the container environment." A **Container** provides operating-system-level virtualisation by abstracting the "user space". One big difference between **Containers** and **VMs** is that unlike VMs, where each **VM** is self-contained with all the operating systems components are within the **VM** package, containers "share" the host system's kernel with other containers.

Container Image: Stored instance of a container that holds a set of software needed to run an application.

Core (physical): An independent computer processing unit that can independently execute CPU instructions and is integrated with other cores on a multiprocessor (chip, integrated circuit die). Please note that the multiprocessor chip is also referred to as a CPU that is placed in a socket of a computer motherboard.

CPU Type: A classification of CPUs by features needed for the execution of computer programs; for example, instruction sets, cache size, number of cores.

Decoupling, Loose Coupling: Loosely coupled system is one in which each of its components has, or makes use of, little or no knowledge of the implementation details of other separate components. Loose coupling is the opposite of tight coupling

Encapsulation: Restricting of direct access to some of an object's components.

External Network: External networks provide network connectivity for a cloud infrastructure tenant to resources outside of the tenant space.

Flavour Capability: The capability of the Cloud Infrastructure Profile, such as CPU Pinning, NUMA or huge pages.

Flavour Geometry: Flavour sizing such as number of vCPUs, RAM, disk, etc.

Fluentd Error! Reference source not found.: An open-source data collector for unified logging layer, which allows data collection and consumption for better use and understanding of data. **Fluentd** is a CNCF graduated project.

Hardware resources: Compute/Storage/Network hardware resources on which the cloud infrastructure platform software, virtual machines and containers run on.

Hugepages: Physical memory is partitioned and accessed using the basic page unit (in Linux default size of 4 KB). Hugepages, typically 2 MB and 1GB size, allows large amounts of memory to be utilised with reduced overhead. In an NFV environment, huge pages are critical to support large memory pool allocation for data packet buffers. This results in fewer Translation Lookaside Buffers (TLB) lookups, which reduces the virtual to physical pages' address translations. Without huge pages enabled high TLB miss rates would occur thereby degrading performance.

Hypervisor: a software that abstracts and isolates workloads with their own operating systems from the underlying physical resources. Also known as a virtual machine monitor (VMM).

Instance: is a virtual compute resource, in a known state such as running or suspended, that can be used like a physical server.

Note: Can be used to specify VM Instance or Container Instance.

Kibana: An open-source data visualisation system.

Monitoring (Capability): Monitoring capabilities are used for the passive observation of workload-specific traffic traversing the Cloud Infrastructure. Note, as with all capabilities, Monitoring may be unavailable or intentionally disabled for security reasons in a given cloud infrastructure instance.

Multi-tenancy: feature where physical, virtual or service resources are allocated in such a way that multiple tenants and their computations and data are isolated from and inaccessible by each other.

Network Function (NF): functional block or application that has well-defined external interfaces and well-defined functional behaviour.

Within **NFV**, a **Network Function** is implemented in a form of **Virtualised NF (VNF)** or a **Cloud Native NF (CNF)**.

NFV Orchestrator (NFVO): Manages the VNF lifecycle and **Cloud Infrastructure** resources (supported by the **VIM**) to ensure an optimised allocation of the necessary resources and connectivity.

Network Function Virtualisation (NFV): The concept of separating network functions from the hardware they run on by using a virtual hardware abstraction layer.

Network Function Virtualisation Infrastructure (NFVI): The totality of all hardware and software components used to build the environment in which a set of virtual applications (VAs) are deployed; also referred to as cloud infrastructure.

Note: The NFVI can span across many locations, e.g., places where data centres or edge nodes are operated. The network providing connectivity between these locations is regarded to be part of the cloud infrastructure. **NFVI** and **VNF** are the top-level conceptual entities in the scope of Network Function Virtualisation. All other components are sub-entities of these two main entities.

Network Service (NS): composition of **Network Function(s)** and/or **Network Service(s)**, defined by its functional and behavioural specification, including the service lifecycle.

Observability: Observability is a measure of how well internal states of a system can be inferred from knowledge of its external outputs.

Platform: A cloud capabilities type in which the cloud service user can deploy, manage and run customer-created or customer-acquired applications using one or more programming languages and one or more execution environments supported by the cloud service provider. Adapted from ITU 0.

Note: This includes the physical infrastructure, Operating Systems, virtualisation/containerisation software and other orchestration, security, monitoring/logging and life-cycle management software.

Prometheus: An open-source monitoring and alerting system.

Quota: An imposed upper limit on specific types of resources, usually used to prevent excessive resource consumption by a given consumer (tenant, VM, container).

Resilience: Resilience is the ability to provide and maintain an acceptable level of service in the face of various faults and challenges to normal operation.

Resource pool: A logical grouping of cloud infrastructure hardware and software resources. A resource pool can be based on a certain resource type (for example, compute, storage and network) or a combination of resource types. A **Cloud Infrastructure** resource can be part of none, one or more resource pools.

Simultaneous Multithreading (SMT): Simultaneous multithreading (SMT) is a technique for improving the overall efficiency of superscalar CPUs with hardware multithreading. SMT permits multiple independent threads of execution on a single core to better utilise the resources provided by modern processor architectures.

Software Defined Storage (SDS): An architecture which consists of the storage software that is independent from the underlying storage hardware. The storage access software provides data request interfaces (APIs) and the SDS controller software provides storage access services and networking.

Software Defined Networking (SDN)

Tenant: cloud service users sharing access to a set of physical and virtual resources, ITU 0.

Note: Tenants represent an independently manageable logical pool of compute, storage and network resources abstracted from physical hardware.

Tenant Instance: refers to a single **Tenant**.

Tenant (Internal) Networks: Virtual networks that are internal to **Tenant Instances**.

User: Natural person, or entity acting on their behalf, associated with a cloud service customer that uses cloud services.

Note: Examples of such entities include devices and applications.

Virtual CPU (vCPU): Represents a portion of the host's computing resources allocated to a virtualised resource, for example, to a virtual machine or a container. One or more vCPUs can be assigned to a virtualised resource.

Virtualised Infrastructure Manager (VIM): Responsible for controlling and managing the Network Function Virtualisation Infrastructure (NFVI) compute, storage and network resources.

Virtual Machine (VM): virtualised computation environment that behaves like a physical computer/server.

Note: A **VM** consists of all of the components (processor (CPU), memory, storage, interfaces/ports, etc.) of a physical computer/server. It is created using sizing information or Compute Flavour.

Virtual Network Function (VNF): a software implementation of a Network Function, capable of running on the Cloud Infrastructure.

VNFs are built from one or more VNF Components (VNFC) and, in most cases, the VNFC is hosted on a single VM or Container.

Virtual resources:

Virtual Compute resource (a.k.a. virtualisation container): partition of a compute node that provides an isolated virtualised computation environment.

Virtual Storage resource: virtualised non-volatile storage allocated to a virtualised computation environment hosting a **VNFC**.

Virtual Networking resource: routes information among the network interfaces of a virtual compute resource and physical network interfaces, providing the necessary connectivity.

Workload: an application (for example **VNF**, or **CNF**) that performs certain task(s) for the users. In the Cloud Infrastructure, these applications run on top of compute resources such as **VMs** or **Containers**. Most relevant workload categories in the context of the Cloud Infrastructure are:

Data Plane Workloads: that perform tasks related to packet handling of the end-to-end communication between applications. These tasks are expected to be very I/O and memory read/write operations intensive.

Control Plane Workloads: that perform tasks related to any other communication between NFs that is not directly related to the end-to-end data communication between applications. For example, this category includes session management, routing or authentication.

Storage Workloads: that perform tasks related to disk storage (either SSD or HDD or other). Examples range from non-intensive router logging to more intensive database read/write operations.

1.8 Abbreviations

Abbreviation/Acronym	Definition
API	Application Programming Interface
DNS	Domain Name System
DPDK	Data Plane Development Kit
ECMP	Equal Cost Multi-Path routing
ETSI	European Telecommunications Standards Institute
FPGA	Field Programmable Gate Array
GB/TB	GigaByte/TeraByte
GPU	Graphics Processing Unit
GRE	Generic Routing Encapsulation
GSMA	GSM Association
GSLB	Global Service Load Balancer
GUI	Graphical User Interface
HA	High Availability
HDD	Hard Disk Drive
HTTP	HyperText Transfer Protocol
HW	Hardware
IaaS (also IaC)	Infrastructure as a Code
IaaS	Infrastructure as a Service
ICMP	Internet Control Message Protocol
IO	Input/Output
IOPS	Input/Output per Second
IPMI	Intelligent Platform Management Interface

Abbreviation/Acronym	Definition
KVM	Kernel-based Virtual Machine
LCM	LifeCycle Management
LDAP	Lightweight Directory Access Protocol
LFN	Linux Foundation Networking
LMA	Logging, Monitoring and Analytics
LVM	Logical Volume Management
MANO	Management ANd Orchestration
MLAG	Multi-chassis Link Aggregation Group
NAT	Network Address Translation
NFS	Network File System
NFV	Network Function Virtualisation
NFVI	Network Function Virtualisation Infrastructure
NIC	Network Interface Card
NPU	Numeric Processing Unit
NTP	Network Time Protocol
NUMA	Non-Uniform Memory Access
OCI	Open Container Initiative
OS	Operating System
OSTK	OpenStack
OVS	Open vSwitch
OWASP	Open Web Application Security Project
PCIe	Peripheral Component Interconnect Express
PCI-PT	PCIe PassThrough
PXE	Preboot Execution Environment
QoS	Quality of Service
RA	Reference Architecture
RA-1	Reference Architecture-1

Abbreviation/Acronym	Definition
RBAC	Role-based Access Control
RBD	RADOS Block Device
REST	Representational state transfer
RI	Reference Implementation
RM	Reference Model
SAST	Static Application Security Testing
SDN	Software Defined Networking
SFC	Service Function Chaining
SLA	Service Level Agreement
SMP	Symmetric Multiprocessing
SMT	Simultaneous multithreading
SNAT	Source Network Address Translation
SNMP	Simple Network Management Protocol
SR-IOV	Single Root Input Output Virtualisation
SSD	Solid State Drive
SSL	Secure Sockets Layer
TCP	Transmission Control Protocol
TLS	Transport Layer Security
ToR	Top of Rack
TPM	Trusted Platform Module
VIM	Virtualised Infrastructure Manager
VLAN	Virtual LAN
VM	Virtual Machine
VNF	Virtual Network Function
VRRP	Virtual Router Redundancy Protocol
VTEP	VXLAN Tunnel End Point
VXLAN	Virtual Extensible LAN

Abbreviation/Acronym	Definition
WAN	Wide Area Network
ZTA	Zero Trust Architecture

1.11 Conventions

The key words “must”, “must not”, “required”, “shall”, “shall not”, “should”, “should not”, “recommended”, “may”, and “optional” in this document are to be interpreted as described in RFC2119 0.

2 Architecture Requirements

2.1 Introduction

This section includes both "Requirements" that must be satisfied in an RA-1 conformant implementation and "Recommendations" that are optional for implementation.

2.2 Reference Model NG 126 Requirements

The tables below contain the requirements from the Reference Model NG126 (RM) to cover the Basic and High-Performance profiles.

To ensure alignment with the infrastructure profile catalogue, the following requirements are referenced through:

1. Those relating to Cloud Infrastructure Software Profiles
2. Those relating to Cloud Infrastructure Hardware Profiles
3. Those relating to Storage Extensions (S extension)
4. Those relating to Network Acceleration Extensions (A extension)
5. Those relating to Cloud Infrastructure Management

Note: "(if offered)" used in the Reference Model has been replaced with "Optional" in the tables below so as to align with RFC2119 0.

2.2.1 Cloud Infrastructure Software Profile Requirements for Compute (source NG126 5.2 0)

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
e.cap.001	Max number of vCPU that can be assigned to a single VM by the Cloud Infrastructure	At least 16	At least 16
e.cap.002	Max memory that can be assigned to a single VM by the Cloud Infrastructure	at least 32 GB	at least 32 GB
e.cap.003	Max storage that can be assigned to a single VM by the Cloud Infrastructure	at least 320 GB	at least 320 GB
e.cap.004	Max number of connection points that can be assigned to a single VM by the Cloud Infrastructure	6	6
e.cap.005	Max storage that can be attached / mounted to VM by the Cloud Infrastructure	Up to 16TB1	Up to 16TB1
e.cap.006/ infra.com.cfg.003	CPU pinning support	Not required	Must support
e.cap.007/ infra.com.cfg.002	NUMA support	Not required	Must support
e.cap.018/ infra.com.cfg.005	Simultaneous Multithreading (SMT) enabled	Not required	Must support

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
i.cap.018/ infra.com.cfg.004	Huge Pages configured	Not required	Must support

Table 1 Reference Model Requirements: Cloud Infrastructure Software Profile Capabilities

2.2.1.1 Cloud Infrastructure Software Profile Extensions Requirements for Compute

Reference	Description	Profile Extensions	Profile Extra-Specs
e.cap.008/ infra.com.acc.cfg .001	IPSec Acceleration using the virtio-ipsec interface	Compute Intensive GPU	
e.cap.010/ infra.com.acc.cfg .002	Transcoding Acceleration	Compute Intensive GPU	Video Transcoding
e.cap.011/ infra.com.acc.cfg .003	Programmable Acceleration	Firmware-programmable adapter	Accelerator
e.cap.012	Enhanced Cache Management: L=Lean; E=Equal; X=eXpanded	E	E
e.cap.014/ infra.com.acc.cfg .004	Hardware coprocessor support (GPU/NPU)	Compute Intensive GPU	
e.cap.016/ infra.com.acc.cfg .005	FPGA/other Acceleration H/W	Firmware-programmable adapter	

Table 2 Cloud Infrastructure Software Profile Extensions Requirements for Compute

2.2.2 Cloud Infrastructure Software Profile Requirements for Networking (source NG126 5.2.3 0)

The features and configuration requirements related to virtual networking for the two (2) types of Cloud Infrastructure Profiles are specified below followed by networking bandwidth requirements.

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
infra.net.cfg.001	IO virtualisation using virtio1.1	Must support	Must support
infra.net.cfg.002	The overlay network encapsulation protocol needs to enable ECMP in the underlay to take advantage of the scale-out features of the network fabric	Must support VXLAN, MPLSoUDP, GENEVE, other	<i>No requirement specified</i>
infra.net.cfg.003	Network Address Translation	Must support	Must support
infra.net.cfg.004	Security Groups	Must support	Must support
infra.net.cfg.005	SFC support	Not required	Must support
infra.net.cfg.006	Traffic patterns symmetry	Must support	Must support

Table 3 Reference Model Requirements - Virtual Networking

The required number of connection points to a VM is described in e.cap.004 in **Error! Reference source not found..** The table below specifies the required bandwidth of those connection points.

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
n1, n2, n3, n4, n5, n6	1, 2, 3, 4, 5, 6 Gbps	Must support	Must support
n10, n20, n30, n40, n50, n60	10, 20, 30, 40, 50, 60 Gbps	Must support	Must support
n25, n50, n75, n100, n125, n150	25, 50, 75, 100, 125, 150 Gbps	Optional	Must support
n50, n100, n150, n200, n250, n300	50, 100, 150, 200, 250, 300 Gbps	Optional	Must support
n100, n200, n300, n400, n500, n600	100, 200, 300, 400, 500, 600 Gbps	Optional	Must support

Table 4 Reference Model Requirements - Network Interface Specifications

2.2.2.1 Cloud Infrastructure Software Profile Extensions Requirements for Networking

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
e.cap.013/ infra.hw.nac.cfg.004	SR-IOV over PCI-PT	N	Y
e.cap.019/ infra.net.acc.cfg.001	vSwitch optimisation (DPDK)	N	Y
e.cap.015/ infra.net.acc.cfg.002	SmartNIC (for HW Offload)	N	Optional
e.cap.009/ infra.net.acc.cfg.003	Crypto acceleration	N	Optional
infra.net.acc.cfg.004	Crypto Acceleration Interface	N	Optional

Table 5 Cloud Infrastructure Software Profile Extensions Requirements for Networking

2.2.3 Cloud Infrastructure Software Profile Requirements for Storage (source NG126 5.2 0)

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
infra.stg.cfg.002	Storage Block	Must support	Must support
infra.stg.cfg.003	Storage with replication	Not required	Must support
infra.stg.cfg.004	Storage with encryption	Must support	Must support
infra.stg.acc.cfg.001	Storage IOPS oriented	Not required	Must support
infra.stg.acc.cfg.002	Storage capacity oriented	Not required	Not required

Table 6 Reference Model Requirements - Cloud Infrastructure Software Profile Requirements for Storage

2.2.3.1 Cloud Infrastructure Software Profile Extensions Requirements for Storage

Reference	Description	Profile Extensions	Profile Extra-Specs
infra.stg.acc.cfg.001	Storage IOPS oriented	Storage Intensive High-performance storage	
infra.stg.acc.cfg.002	Storage capacity oriented	High Capacity	

Table 7 Reference Model Requirements - Cloud Infrastructure Software Profile Extensions Requirements for Storage

2.2.4 Cloud Infrastructure Hardware Profile Requirements (source NG126 5.4 0)

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
infra.hw.001	CPU Architecture (Values such as x64, ARM, etc.)		
infra.hw.cpu.cfg.001	Minimum number of CPU (Sockets)	2	2
infra.hw.cpu.cfg.002	Minimum number of Cores per CPU	20	20
infra.hw.cpu.cfg.003	NUMA	Not required	Must support
infra.hw.cpu.cfg.004	Simultaneous Multithreading/Symmetric Multiprocessing (SMT/SMP)	Must support	Must support
infra.hw.stg.hdd.cfg.001	Local Storage HDD	No requirement specified	No requirement specified
infra.hw.stg.ssd.cfg.002	Local Storage SSD	Should support	Should support
infra.hw.nic.cfg.001	Total Number of NIC Ports available in the host	4	4

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
infra.hw.nic.cfg.002	Port speed specified in Gbps (minimum values)	10	25
infra.hw.pci.cfg.001	Number of PCIe slots available in the host	8	8
infra.hw.pci.cfg.002	PCIe speed	Gen 3	Gen 3
infra.hw.pci.cfg.003	PCIe Lanes	8	8
infra.hw.nac.cfg.003	Compression	No requirement specified	No requirement specified

Table 8 Reference Model Requirements - Cloud Infrastructure Hardware Profile Requirements

2.2.5 Cloud Infrastructure Hardware Profile-Extensions Requirements (source NG126 5.4 0)

Reference	Description	Requirement for Basic Profile	Requirement for High-Performance Profile
e.cap.014/ infra.hw.cac.cfg.001	GPU	N	Optional
e.cap.016/ infra.hw.cac.cfg.002	FPGA/other Acceleration H/W	N	Optional
e.cap.009/ infra.hw.nac.cfg.001	Crypto Acceleration	N	Optional
e.cap.015/ infra.hw.nac.cfg.002	SmartNIC	N	Optional
infra.hw.nac.cfg.003	Compression	Optional	Optional
e.cap.013/ infra.hw.nac.cfg.004	SR-IOV over PCI-PT	N	Yes

Table 9 Reference Model Requirements - Cloud Infrastructure Hardware Profile-Extensions Requirements

2.2.6 Cloud Infrastructure Management Requirements (source NG126 4.1.5 0)

Reference	Description	Requirement (common to all Profiles)
e.man.001	Capability to allocate virtual compute resources to a workload	Must support
e.man.002	Capability to allocate virtual storage resources to a workload	Must support
e.man.003	Capability to allocate virtual networking resources to a workload	Must support
e.man.004	Capability to isolate resources between tenants	Must support
e.man.005	Capability to manage workload software images	Must support

Reference	Description	Requirement (common to all Profiles)
e.man.006	Capability to provide information related to allocated virtualized resources per tenant	Must support
e.man.007	Capability to notify state changes of allocated resources	Must support
e.man.008	Capability to collect and expose performance information on virtualized resources allocated	Must support
e.man.009	Capability to collect and notify fault information on virtualized resources	Must support

Table 10 Reference Model Requirements - Cloud Infrastructure Management Requirements

2.2.7 Cloud Infrastructure Security Requirements

2.2.7.1 System Hardening (source NG126 7.9.1 0)

Ref #	sub-category	Description	Traceability
sec.gen.001	Hardening	The Platform must maintain the specified configuration.	Security LCM, Cloud Infrastructure and VIM configuration management
sec.gen.002	Hardening	All systems part of Cloud Infrastructure must support password hardening as defined in CIS Password Policy Guide Error! Reference source not found..	Password policy
sec.gen.003	Hardening	All servers part of Cloud Infrastructure must support a root of trust and secure boot.	Server boot hardening
sec.gen.004	Hardening	The Operating Systems of all the Cloud Infrastructure servers must be hardened by removing or disabling unnecessary services, applications and network protocols, configuring operating system user authentication, configuring resource controls, installing and configuring additional	Function and Software

Ref #	sub-category	Description	Traceability
		security controls where needed, and testing the security of the Operating System (NIST SP 800-123).	
sec.gen.005	Hardening	The Platform must support Operating System level access control.	System Access
sec.gen.006	Hardening	The Platform must support Secure logging. Logging with root account must be prohibited when root privileges are not required.	System Access
sec.gen.007	Hardening	All servers part of Cloud Infrastructure must be Time synchronized with authenticated Time service.	Security Logs Time Synchronisation
sec.gen.008	Hardening	All servers part of Cloud Infrastructure must be regularly updated to address security vulnerabilities.	Patches, Security LCM
sec.gen.009	Hardening	The Platform must support Software integrity protection and verification.	Integrity of OpenStack components configuration, Image Security
sec.gen.010	Hardening	The Cloud Infrastructure must support encrypted storage, for example, block, object and file storage, with access to encryption keys restricted based on a need to know (Error! Reference source not found.).	Confidentiality and Integrity of tenant data (sec.ci.001)
sec.gen.012	Hardening	The Operator must ensure that only authorized actors have physical access to the underlying infrastructure.	This requirement's verification goes beyond the Reference Architecture testing scope
sec.gen.013	Hardening	The Platform must ensure that only authorized actors have logical access to the underlying infrastructure.	System Access
sec.gen.015	Hardening	Any change to the Platform must be logged as a security event, and the logged event must include the identity of the entity making the change, the	Security LCM

Ref #	sub-category	Description	Traceability
		change, the date and the time of the change.	

Table 11 Reference Model Requirements - System Hardening Requirements

2.2.7.2 Platform and Access (source NG126 7.9.2 0)

Ref #	sub-category	Description	Traceability
sec.sys.001	Access	The Platform must support authenticated and secure access to API, GUI and command line interfaces	RBAC
sec.sys.002	Access	The Platform must support Traffic Filtering for workloads (for example, Fire Wall).	Workload Security
sec.sys.003	Access	The Platform must support Secure and encrypted communications, and confidentiality and integrity of network traffic.	Confidentiality and Integrity of communications (sec.ci.001)
sec.sys.004	Access	The Cloud Infrastructure must support authentication, integrity and confidentiality on all network channels.	Confidentiality and Integrity of communications (sec.ci.001)
sec.sys.005	Access	The Cloud Infrastructure must segregate the underlay and overlay networks.	Confidentiality and Integrity of communications (sec.ci.001)
sec.sys.006	Access	The Cloud Infrastructure must be able to utilize the Cloud Infrastructure Manager identity lifecycle management capabilities.	Identity Security
sec.sys.007	Access	The Platform must implement controls enforcing separation of duties and privileges, least privilege use and least common mechanism (Role-Based Access Control).	RBAC

Ref #	sub-category	Description	Traceability
sec.sys.008	Access	The Platform must be able to assign the Entities that comprise the tenant networks to different trust domains. (Communication between different trust domains is not allowed, by default.)	Workload Security
sec.sys.009	Access	The Platform must support creation of Trust Relationships between trust domains. These may be unidirectional relationships where the trusting domain trusts another domain (the “trusted domain”) to authenticate users for them or to allow access to its resources from the trusted domain. In a bidirectional relationship, both domains are “trusting” and “trusted”.	
sec.sys.010	Access	For two or more domains without existing trust relationships, the Platform must not allow the effect of an attack on one domain to impact the other domains either directly or indirectly.	
sec.sys.011	Access	The Platform must not reuse the same authentication credentials (e.g., key pairs) on different Platform components (e.g., different hosts, or different services).	System Access
sec.sys.012	Access	The Platform must protect all secrets by using strong encryption techniques and storing the protected secrets externally from the component (e.g., in OpenStack Barbican)	
sec.sys.013	Access	The Platform must generate secrets dynamically as and when needed.	
sec.sys.015	Access	The Platform must not contain back door entries (unpublished access points, APIs, etc.).	
sec.sys.016	Access	Login access to the Platform's components must be through encrypted protocols such as SSH v2 or TLS v1.2 or higher. Note: Hardened jump servers isolated from external networks are recommended	Security LCM

Ref #	sub-category	Description	Traceability
sec.sys.017	Access	The Platform must provide the capability of using digital certificates that comply with X.509 standards issued by a trusted Certification Authority.	Confidentiality and Integrity of communications (sec.ci.001)
sec.sys.018	Access	The Platform must provide the capability of allowing certificate renewal and revocation.	
sec.sys.019	Access	The Platform must provide the capability of testing the validity of a digital certificate (CA signature, validity period, non-revocation, identity).	

Table 12 Reference Model Requirements - Platform and Access Requirements

2.2.7.3 Confidentiality and Integrity (source NG126 7.9.3 0)

Ref #	sub-category	Description	Traceability
sec.ci.001	Confidentiality/Integrity	The Platform must support Confidentiality and Integrity of data at rest and in transit.	Confidentiality and Integrity
sec.ci.003	Confidentiality/Integrity	The Platform must support Confidentiality and Integrity of data related metadata.	
sec.ci.004	Confidentiality	The Platform must support Confidentiality of processes and restrict information sharing with only the process owner (e.g., tenant).	
sec.ci.005	Confidentiality/Integrity	The Platform must support Confidentiality and Integrity of process-related metadata and restrict information sharing with only the process owner (e.g., tenant).	
sec.ci.006	Confidentiality/Integrity	The Platform must support Confidentiality and Integrity of workload resource utilization (RAM, CPU, Storage, Network I/O, cache, hardware offload) and restrict information sharing with only the workload owner (e.g., tenant).	
sec.ci.007	Confidentiality/Integrity	The Platform must not allow Memory Inspection by any actor	

Ref #	sub-category	Description	Traceability
		other than the authorized actors for the Entity to which Memory is assigned (e.g., tenants owning the workload), for Lawful Inspection, and for secure monitoring services. Administrative access must be managed using Platform Identity Lifecycle Management.	
sec.ci.008	Confidentiality	The Cloud Infrastructure must support tenant networks segregation.	Workload Security

Table 13 Reference Model Requirements - Confidentiality and Integrity Requirements

2.2.7.4 Workload Security (source NG126 7.9.4 0)

Ref #	sub-category	Description	Traceability
sec.wl.001	Workload	The Platform must support Workload placement policy.	Workload Security
sec.wl.002	Workload	The Cloud Infrastructure must provide methods to ensure the platform's trust status and integrity (e.g., remote attestation, Trusted Platform Module).	
sec.wl.003	Workload	The Platform must support secure provisioning of Workloads.	Workload Security
sec.wl.004	Workload	The Platform must support Location assertion (for mandated in-country or location requirements).	Workload Security
sec.wl.005	Workload	The Platform must support the separation of production and non-production Workloads.	This requirement's verification goes beyond the Reference Architecture testing scope
sec.wl.006	Workload	The Platform must support the separation of Workloads based on their categorization (for example, payment card information, healthcare, etc.)	Workload Security

Table 14 Reference Model Requirements - Workload Security Requirements

2.2.7.5 Image Security (source NG126 7.9.5 0)

Ref #	sub-category	Description	Traceability
sec.img.001	Image	Images from untrusted sources must not be used.	Image Security
sec.img.002	Image	Images must be scanned to be maintained free from known vulnerabilities.	Image Security
sec.img.003	Image	Images must not be configured to run with privileges higher than the privileges of the actor authorized to run them.	
sec.img.004	Image	Images must only be accessible to authorized actors.	Confidentiality and Integrity of communications (sec.ci.001)
sec.img.005	Image	Image Registries must only be accessible to authorized actors.	Confidentiality and Integrity of communications (sec.ci.001)
sec.img.006	Image	Image Registries must only be accessible over networks that enforce authentication, integrity and confidentiality.	Confidentiality and Integrity of communications (sec.ci.001)
sec.img.007	Image	Image registries must be clear of vulnerable and out of date versions.	Confidentiality and Integrity of communications (sec.ci.001), Image Security

Table 15 Reference Model Requirements – Image Security Requirements**2.2.7.6 Security LCM (source NG126 7.9.6 0)**

Ref #	sub-category	Description	Traceability
sec.lcm.001	LCM	The Platform must support Secure Provisioning, Availability, and Deprovisioning (Secure Clean-Up) of workload resources where Secure Clean-Up includes tear-down, defense against virus or other attacks.	Monitoring and Security Audit

Ref #	sub-category	Description	Traceability
sec.lcm.002	LCM	The Cloud Operator must use management protocols limiting security risk such as SNMPv3, SSH v2, ICMP, NTP, syslog and TLS v1.2 or higher.	Security LCM
sec.lcm.003	LCM	The Cloud Operator must implement and strictly follow change management processes for Cloud Infrastructure, Cloud Infrastructure Manager and other components of the cloud, and Platform change control on hardware.	Monitoring and Security Audit
sec.lcm.005	LCM	Platform must provide logs and these logs must be monitored for anomalous behavior.	Monitoring and Security Audit
sec.lcm.006	LCM	The Platform must verify the integrity of all Resource management requests.	Confidentiality and Integrity of tenant data (sec.ci.001)
sec.lcm.007	LCM	The Platform must be able to update newly instantiated, suspended, hibernated, migrated, and restarted images with current time information.	
sec.lcm.008	LCM	The Platform must be able to update newly instantiated, suspended, hibernated, migrated and restarted images with relevant DNS information.	
sec.lcm.009	LCM	The Platform must be able to update the tag of newly instantiated, suspended, hibernated, migrated, and restarted images with relevant geolocation (geographical) information.	
sec.lcm.010	LCM	The Platform must log all changes to geolocation along with the mechanisms and sources of location information (i.e., GPS, IP block, and timing).	
sec.lcm.011	LCM	The Platform must implement Security life cycle management processes including the proactive update and patching of all deployed Cloud Infrastructure	Patches

Ref #	sub-category	Description	Traceability
		software.	
sec.lcm.012	LCM	The Platform must log any access privilege escalation.	What to Log / What NOT to Log

Table 16 Reference Model Requirements – Security LCM Requirements

2.2.7.7 Monitoring and Security Audit (source NG126 7.9.7 0)

The Platform is assumed to provide configurable alerting and notification capability and the operator is assumed to have automated systems, policies, and procedures to act on alerts and notifications in a timely fashion. In the following the monitoring and logging capabilities can trigger alerts and notifications for appropriate action.

Ref #	sub-category	Description	Traceability
sec.mon.001	Monitoring/ Audit	Platform must provide logs and these logs must be regularly monitored for events of interest. The logs must contain the following fields: event type, date/time, protocol, service, or program used for access, success/failure, login ID or process ID, IP address and ports (source and destination) involved.	Creating Logs, Required Fields
sec.mon.002	Monitoring	Security logs must be time synchronized.	Security Logs Time Synchronisation
sec.mon.003	Monitoring	The Platform must log all changes to time server source, time, date and time zones.	Security Logs Time Synchronisation
sec.mon.004	Audit	The Platform must secure and protect Audit logs (containing sensitive information) both in-transit and at rest.	Security LCM
sec.mon.005	Monitoring/ Audit	The Platform must Monitor, and Audit various behaviors of connection and login attempts to detect access attacks and potential access attempts and take corrective actions accordingly	Confidentiality and Integrity of communications (sec.ci.001), What to Log / What NOT to Log
sec.mon.006	Monitoring/ Audit	The Platform must Monitor, and Audit operations by authorized account access after login to detect malicious operational activity and take corrective actions.	Integrity of OpenStack components configuration, Monitoring and Security Audit
sec.mon.007	Monitoring/ Audit	The Platform must Monitor, and Audit security parameter configurations for compliance with defined security policies.	Integrity of OpenStack components configuration

Ref #	sub-category	Description	Traceability
sec.mon.008	Monitoring/ Audit	The Platform must Monitor, and Audit externally exposed interfaces for illegal access (attacks) and take corrective security hardening measures.	Confidentiality and Integrity of communications (sec.ci.001)
sec.mon.009	Monitoring/ Audit	The Platform must Monitor, and Audit service for various attacks (malformed messages, signaling flooding and replaying, etc.) and take corrective actions accordingly.	Confidentiality and Integrity of communications (sec.ci.001), Monitoring and Security Audit
sec.mon.010	Monitoring/ Audit	The Platform must Monitor, and Audit running processes to detect unexpected or unauthorized processes and take corrective actions accordingly.	Monitoring and Security Audit
sec.mon.011	Monitoring/ Audit	The Platform must Monitor, and Audit logs from infrastructure elements and workloads to detected anomalies in the system components and take corrective actions accordingly.	Creating Logs
sec.mon.012	Monitoring/ Audit	The Platform must Monitor, and Audit Traffic patterns and volumes to prevent malware download attempts.	Confidentiality and Integrity of tenant data (sec.ci.001)
sec.mon.013	Monitoring	The monitoring system must not affect the security (integrity and confidentiality) of the infrastructure, workloads, or the user data (through back door entries).	
sec.mon.015	Monitoring	The Platform must ensure that the Monitoring systems are never starved of resources and must activate alarms when resource utilization exceeds a configurable threshold.	Monitoring and Security Audit
sec.mon.017	Audit	The Platform must audit systems for any missing security patches and take appropriate actions.	Patches

Ref #	sub-category	Description	Traceability
sec.mon.018	Monitoring	The Platform, starting from initialization, must collect and analyze logs to identify security events, and store these events in an external system.	Where to Log
sec.mon.019	Monitoring	The Platform's components must not include an authentication credential, e.g., password, in any logs, even if encrypted.	What to Log / What NOT to Log
sec.mon.020	Monitoring/ Audit	The Platform's logging system must support the storage of security audit logs for a configurable period of time.	Data Retention
sec.mon.021	Monitoring	The Platform must store security events locally if the external logging system is unavailable and shall periodically attempt to send these to the external logging system until successful.	Where to Log

Table 17 Reference Model Requirements – Monitoring and Security Audit Requirements

2.2.7.8 Open Source Software (source NG126 7.9.8 0)

Ref #	sub-category	Description	Traceability
sec.oss.001	Software	Open-source code must be inspected by tools with various capabilities for static and dynamic code analysis.	
sec.oss.002	Software	The CVE (Common Vulnerabilities and Exposures) must be used to identify vulnerabilities and their severity rating for open-source code part of Cloud Infrastructure and workloads software Error! Reference source not found.	
sec.oss.003	Software	High severity rated vulnerabilities must be fixed. Refer to the CVSS (Common Vulnerability Scoring System) to know a vulnerability score.	

sec.oss.004	Software	A dedicated internal isolated repository separated from the production environment must be used to store vetted open-source content.	
-------------	----------	---	--

Table 18 Reference Model Requirements – Open-Source Software Security Requirements

2.2.7.9 IaaS security (source NG126 7.9.9 0)

Secure Code Stage Requirements

Ref #	sub-category	Description	Traceability
sec.code.001	IaaS	SAST -Static Application Security Testing must be applied during Secure Coding stage triggered by Pull, Clone or Commit trigger. Security testing that analyses application source code for software vulnerabilities and gaps against best practices. Example: open source OWASP range of tools.	

Table 19 Reference Model Requirements – IaaS Security Requirements, Secure Code Stage

2.2.7.9.2

Continuous Build, Integration and Testing Stage Requirements

Ref #	sub-category	Description	Traceability
sec.bld.003	IaaS	Container and Image Scan must be applied during the Continuous Build, Integration and Testing stage triggered by Package trigger. Example: A push of a container image to a container registry may trigger a vulnerability scan before the image becomes available in the registry.	

Table 20 Reference Model Requirements – IaaS Security Requirements, Continuous Build, Integration and Testing Stage

Continuous Delivery and Deployment Stage Requirements

Ref #	sub-category	Description	Traceability
2793 sec.del.001	laaC	Image Scan must be applied during the Continuous Delivery and Deployment stage triggered by Publish to Artifact and Image Repository trigger. Example: GitLab uses the open-source Clair engine for container image scanning.	
sec.del.002	laaC	Code Signing must be applied during the Continuous Delivery and Deployment stage triggered by Publish to Artifact and Image Repository trigger. Code Signing provides authentication to assure that downloaded files are from the publisher named on the certificate.	
sec.del.004	laaC	Component Vulnerability Scan must be applied during the Continuous Delivery and Deployment stage triggered by Instantiate Infrastructure trigger. The vulnerability scanning system is deployed on the cloud platform to detect security vulnerabilities of specified components through scanning and to provide timely security protection. Example: OWASP Zed Attack Proxy (ZAP).	

Table 21 Reference Model Requirements – IaaS Security Requirements, Continuous Delivery and Deployment Stage

Runtime Defense and Monitoring Requirements

Ref #	sub-category	Description	Traceability
2.2.7.10 2794 sec.run.001	iaaC	Component Vulnerability Monitoring must be continuously applied during the Runtime Defense and Monitoring stage. Security technology that monitors components like virtual servers and assesses data, applications, and infrastructure for security risks.	

Table 22 Reference Model Requirements – IaaS Security Requirements, Runtime Defence and Monitoring Stage

2.2.7.10 Compliance with Standards (source NG126 7.9.10 0)

Ref #	sub-category	Description	Traceability
sec.std.012	Standards	The Public Cloud Operator must , and the Private Cloud Operator may be certified to be compliant with the International Standard on Awareness Engagements (ISAE) 3402 (in the US: SSAE 16);	

Table 23 Reference Model Requirements – Cloud Infrastructure Security Requirements

2.3 Architecture and OpenStack Requirements

“Architecture” in this section refers to Cloud infrastructure (referred to as NFVI by ETSI) + VIM (as specified in NG126 0 section 3).

2.3.1 General Requirements

Ref #	sub-category	Description	Traceability
gen.ost.01	Open source	The Architecture must use OpenStack APIs.	Consolidated Set of APIs
gen.ost.02	Open source	The Architecture must support dynamic request and configuration of virtual resources (compute, network, storage) through OpenStack APIs.	Consolidated Set of APIs

gen.rsl.01	Resiliency	The Architecture must support resilient OpenStack components that are required for the continued availability of running workloads.	
gen.avl.01	Availability	The Architecture must provide High Availability for OpenStack components.	Underlying Resources

Table 24 General Requirements**2.3.2 Infrastructure Requirements**

Ref #	sub-category	Description	Traceability
inf.com.01	Compute	The Architecture must provide compute resources for VM instances.	Cloud Workload Services
inf.com.04	Compute	The Architecture must be able to support multiple CPU type options to support various infrastructure profiles (Basic and High Performance).	Support for Cloud Infrastructure Profiles and
inf.com.05	Compute	The Architecture must support Hardware Platforms with NUMA capabilities.	Support for Cloud Infrastructure Profiles and
inf.com.06	Compute	The Architecture must support CPU Pinning of the vCPUs of a VM instance.	Support for Cloud Infrastructure Profiles and
inf.com.07	Compute	The Architecture must support different hardware configurations to support various infrastructure profiles (Basic and High Performance).	Cloud partitioning: Host Aggregates, Availability Zones
inf.com.08	Compute	The Architecture must support allocating a certain number of host cores for all non-tenant workloads such as for OpenStack services. SMT threads can be allocated to individual OpenStack services or their components.	“Dedicating host cores to certain workloads” Error! Reference source not found.. Please see example, “Configuring libvirt compute nodes for CPU pinning” Error! Reference source not found..

Ref #	sub-category	Description	Traceability
inf.com.09	Compute	The Architecture must ensure that the host cores assigned to non-tenant and tenant workloads are SMT aware: that is, a host core and its associated SMT threads are either all assigned to non-tenant workloads, or all assigned to tenant workloads.	Achieved through configuring the "cpu_dedicated_set" and "cpu_shared_set" parameters in nova.conf correctly.
inf.stg.01	Storage	The Architecture must provide remote (not directly attached to the host) Block storage for VM Instances.	Storage
inf.stg.02	Storage	The Architecture must provide Object storage for VM Instances. Operators may choose not to implement Object Storage but must be cognizant of the risk of "Compliant VNFs" failing in their environment.	OpenStack Swift Service (Swift)
inf.ntw.01	Network	The Architecture must provide virtual network interfaces to VM instances.	Neutron
inf.ntw.02	Network	The Architecture must include capabilities for integrating SDN controllers to support provisioning of network services, from the OpenStack Neutron service, such as networking of VTEPs to the Border Edge based VRFs.	Virtual Networking – 3rd party SDN solution
inf.ntw.03	Network	The Architecture must support low latency and high throughput traffic needs.	Network Fabric
inf.ntw.05	Network	The Architecture must allow for East/West tenant traffic within the cloud (via tunneled encapsulation overlay such as VXLAN or Geneve).	Network Fabric
inf.ntw.07	Network	The Architecture must support network resiliency [Terminology].	Network
inf.ntw.10	Network	The Cloud Infrastructure Network Fabric must be capable of enabling highly available (Five 9's or better)	Network

Ref #	sub-category	Description	Traceability
		Cloud Infrastructure.	
inf.ntw.15	Network	The Architecture must support multiple networking options for Cloud Infrastructure to support various infrastructure profiles (Basic and High Performance).	“Neutron ML2-plugin Integration” [Neutron Extensions] and OpenStack Neutron Plugins Error! Reference source not found..
inf.ntw.16	Network	The Architecture must support dual stack Ipv4 and Ipv6 for tenant networks and workloads.	

Table 25 Infrastructure Requirements

2.3.3 VIM Requirements

Ref #	sub-category	Description	Traceability
vim.01	General	The Architecture must allow infrastructure resource sharing.	Consumable Infrastructure Resources and Services
vim.03	General	The Architecture must allow VIM to discover and manage Cloud Infrastructure resources.	Placement
vim.05	General	The Architecture must include image repository management.	Glance
vim.07	General	The Architecture must support multi-tenancy.	Multi-Tenancy (execution environment)
vim.08	General	The Architecture must support resource tagging.	“OpenStack Resource Tags” Error! Reference source not found.

Table 26 VIM Requirements

2.3.4 Interfaces & APIs Requirements

Ref #	sub-category	Description	Traceability
int.api.01	API	The Architecture must provide APIs to access the authentication service and the	Keystone

Ref #	sub-category	Description	Traceability
		associated mandatory features detailed in section 5.	
int.api.02	API	The Architecture must provide APIs to access the image management service and the associated mandatory features detailed in section 5.	Glance
int.api.03	API	The Architecture must provide APIs to access the block storage management service and the associated mandatory features detailed in section 5.	Cinder
int.api.04	API	The Architecture must provide APIs to access the object storage management service and the associated mandatory features detailed in section 5.	Swift
int.api.05	API	The Architecture must provide APIs to access the network management service and the associated mandatory features detailed in section 5.	Neutron
int.api.06	API	The Architecture must provide APIs to access the compute resources management service and the associated mandatory features detailed in section 5.	Nova
int.api.07	API	The Architecture must provide GUI access to tenant facing cloud platform core services except at Edge/Far Edge clouds.	Horizon
int.api.08	API	The Architecture must provide APIs needed to discover and manage Cloud Infrastructure resources.	Placement
int.api.09	API	The Architecture must provide APIs to access the orchestration service.	Heat
int.api.10	API	The Architecture must expose the latest version and microversion of the APIs for the given OpenStack release for each of the OpenStack core services.	Core OpenStack Services APIs

Table 27 Interfaces and APIs Requirements**2.3.5 Tenant Requirements**

Ref #	sub-category	Description	Traceability
tnt.gen.01	General	The Architecture must support self-service dashboard (GUI) and APIs for users to deploy, configure and manage their workloads.	Horizon and Cloud Workload Services

Table 28 Tenant Requirements**2.3.6 Operations and LCM**

Ref #	sub-category	Description	Traceability
lcm.gen.01	General	The Architecture must support zero downtime of running workloads when the number of compute hosts and/or the storage capacity is being expanded or unused capacity is being removed.	
lcm.adp.02	Automated deployment	The Architecture must support upgrades of software, provided by the cloud provider, so that the running workloads are not impacted (viz., hitless upgrades). Please note that this means that the existing data plane services should not fail (go down).	

Table 29 LCM Requirements**2.3.7 Assurance Requirements**

Ref #	sub-category	Description	Traceability
asr.mon.01	Integration	The Architecture must include integration with various infrastructure components to support collection of telemetry for assurance monitoring and network intelligence.	
asr.mon.03	Monitoring	The Architecture must allow for the collection and dissemination of performance and fault information.	

Ref #	sub-category	Description	Traceability
asr.mon.04	Network	The Cloud Infrastructure Network Fabric and Network Operating System must provide network operational visibility through alarming and streaming telemetry services for operational management, engineering planning, troubleshooting, and network performance optimisation.	

Table 30 Assurance Requirements

2.4 Architecture and OpenStack Recommendations

The requirements listed in this section are optional and are not required in order to be deemed a conformant implementation.

2.4.1 General Recommendations

Ref #	sub-category	Description	Notes
gen.cnt.01	Cloud nativeness	The Architecture should consist of stateless service components. However, where state is required, it must be kept external to the component.	OpenStack consists of both stateless and stateful services where the stateful services utilize a database. For latter see "Configuring the stateful services" Error! Reference source not found.
gen.cnt.02	Cloud nativeness	The Architecture should consist of service components implemented as microservices that are individually dynamically scalable.	
gen.scl.01	Scalability	The Architecture should support policy driven auto-scaling.	This requirement is currently not addressed but will likely be supported through Senlin Error! Reference source not found. , cluster management service.
gen.rsl.02	Resiliency	The Architecture should support resilient OpenStack service components that are not subject to gen.rsl.01.	

Table 31 General Recommendations**2.4.2 Infrastructure Recommendations**

Ref #	sub-category	Description	Notes
inf.com.02	Compute	The Architecture should include industry standard hardware management systems at both HW device level (embedded) and HW platform level (external to device).	
inf.com.03	Compute	The Architecture should support Symmetric Multiprocessing with shared memory access as well as Simultaneous Multithreading.	
inf.stg.08	Storage	The Architecture should allow use of externally provided large archival storage for its Backup / Restore / Archival needs.	
inf.stg.09	Storage	The Architecture should make available all non-host OS / Hypervisor / Host systems storage as network-based Block, File or Object Storage for tenant/management consumption.	
inf.stg.10	Storage	The Architecture should provide local Block storage for VM Instances.	Virtual Storage
inf.ntw.04	Network	The Architecture should support service function chaining.	
inf.ntw.06	Network	The Architecture should support Distributed Virtual Routing (DVR) to allow compute nodes to route traffic efficiently.	
inf.ntw.08	Network	The Cloud Infrastructure Network Fabric should embrace the concepts of open networking and disaggregation using commodity networking hardware and disaggregated Network Operating Systems.	
inf.ntw.09	Network	The Cloud Infrastructure Network Fabric should embrace open-based standards and technologies.	

Ref #	sub-category	Description	Notes
inf.ntw.11	Network	The Cloud Infrastructure Network Fabric should be architected to provide a standardized, scalable, and repeatable deployment model across all applicable Cloud Infrastructure sites.	
inf.ntw.17	Network	The Architecture should use dual stack Ipv4 and Ipv6 for Cloud Infrastructure internal networks.	
inf.acc.01	Acceleration	The Architecture should support Application Specific Acceleration (exposed to VNFs).	Acceleration
inf.acc.02	Acceleration	The Architecture should support Cloud Infrastructure Acceleration (such as SmartNICs).	"OpenStack Future – Specs defined" Error! Reference source not found.
inf.acc.03	Acceleration	The Architecture may rely on SR-IOV PCI-Pass through to provide acceleration to VNFs.	
inf.img.01	Image	The Architecture should make the immutable images available via location independent means.	Glance

Table 32 Infrastructure Recommendations

2.4.3 VIM Recommendations

Ref #	sub-category	Description	Notes
vim.02	General	The Architecture should support deployment of OpenStack components in containers.	Containerised OpenStack Services
vim.04	General	The Architecture should support Enhanced Platform Awareness (EPA) only for discovery of infrastructure resource capabilities.	
vim.06	General	The Architecture should allow orchestration solutions to be integrated with VIM.	
vim.09	General	The Architecture should support horizontal scaling of OpenStack core services.	

Table 33 VIM Recommendations

2.4.4 Interfaces and APIs Recommendations

Ref #	sub-category	Description	Notes
int.acc.01	Acceleration	The Architecture should provide an open and standard acceleration interface to VNFs.	

Table 34 Interfaces and APIs Recommendations

2.4.5 Tenant Recommendations

This section is left blank for future use.

2.4.6 Operations and LCM Recommendations

Ref #	sub-category	Description	Notes
lcm.adp.01	Automated deployment	The Architecture should allow for “cookie cutter” automated deployment, configuration, provisioning, and management of multiple Cloud Infrastructure sites.	
lcm.adp.03	Automated deployment	The Architecture should support hitless upgrade of all software provided by the cloud provider that are not covered by lcm.adp.02. Whenever hitless upgrades are not feasible, attempt should be made to minimize the duration and nature of impact.	
lcm.adp.04	Automated deployment	The Architecture should support declarative specifications of hardware and software assets for automated deployment, configuration, maintenance, and management.	
lcm.adp.05	Automated deployment	The Architecture should support automated process for Deployment and life-cycle management of VIM Instances.	
lcm.cid.02	CI/CD	The Architecture should support integrating with CI/CD Toolchain for Cloud Infrastructure and VIM components Automation.	

Table 35 LCM Recommendations

2.4.7 Assurance Recommendations

Ref #	sub-category	Description	Notes
asr.mon.02	Monitoring	The Architecture should support Network Intelligence capabilities that allow richer diagnostic capabilities which take as input broader set of data across the network and from VNF workloads.	

Table 36 Assurance Recommendations

2.4.8 Security Recommendations

2.4.8.1 System Hardening (source NG126 7.9.1 0)

Ref #	sub-category	Description	Notes
sec.gen.011	Hardening	The Cloud Infrastructure should support Read and Write only storage partitions (write only permission to one or more authorized actors).	
sec.gen.014	Hardening	All servers part of Cloud Infrastructure should support measured boot and an attestation server that monitors the measurements of the servers.	

Table 37 System Hardening Recommendations

2.4.8.2 Platform and Access (source NG126 7.9.2 0)

Ref #	sub-category	Description	Notes
sec.sys.014	Access	The Platform should use Linux Security Modules such as SELinux to control access to resources.	
sec.sys.020	Access	The Cloud Infrastructure architecture should rely on Zero Trust principles to build a secure by design environment.	Zero Trust Architecture (ZTA) described in NIST SP 800-207 0

Table 38 Platform and Access Recommendations

2.4.9 Confidentiality and Integrity (source NG126 7.9.3 0)

Ref #	sub-category	Description	Notes
sec.ci.002	Confidentiality/Integrity	The Platform should support self-encrypting storage devices	
sec.ci.009	Confidentiality/Integrity	For sensitive data encryption, the key management service should leverage a Hardware Security Module to manage and protect cryptographic keys.	

Table 39 Confidentiality and Integrity Recommendations

2.4.9.1 Workload Security (source NG126 7.9.4 0)

Ref #	sub-category	Description	Notes
sec.wl.007	Workload	The Operator should implement processes and tools to verify VNF authenticity and integrity.	

Table 40 Workload Security Recommendations

2.4.9.2 Image Security (source NG126 7.9.5 0)

This section is left blank for future use.

2.4.9.3 Security LCM (source NG126 7.9.6 0)

Ref #	sub-category	Description	Notes
sec.lcm.004	LCM	The Cloud Operator should support automated templated approved changes; Templated approved changes for automation where available	

Table 41 LCM Security Recommendations

2.4.9.4 Monitoring and Security Audit (source NG126 7.9.7 0)

The Platform is assumed to provide configurable alerting and notification capability and the operator is assumed to have automated systems, policies and procedures to act on alerts and notifications in a timely fashion. In the following the monitoring and logging capabilities can trigger alerts and notifications for appropriate action.

Ref #	sub-category	Description	Notes
sec.mon.014	Monitoring	The Monitoring systems should not impact IaaS, PaaS, and SaaS SLAs including availability SLAs	
sec.mon.016	Monitoring	The Platform Monitoring components should follow security best practices for auditing, including secure logging and tracing	

Table 42 Monitoring and Security Audit Recommendations

2.4.9.5 Open Source Software Security (source NG126 7.9.8 0)

Ref #	sub-category	Description	Notes
sec.oss.004	Software	A Software Bill of Materials (SBOM) should be provided or build and maintained to identify the software components and their origins. Inventory of software components	“Software Bill of Materials (SBOM)” Error! Reference source not found.

Table 43 Open Source Software Security Recommendations

2.4.9.6 IaaS security (source NG126 7.9.9 0)

2.4.9.6.1

Secure Design and Architecture Stage

Ref #	sub-category	Description	Notes
sec.arch.001	IaaS	Threat Modelling methodologies and tools should be used during the Secure Design and Architecture stage triggered by Software Feature Design trigger. Methodology to identify and understand threats impacting a resource or set of resources.	It may be done manually or using tools like open source OWASP Threat Dragon
sec.arch.002	IaaS	Security Control Baseline Assessment should be performed during the Secure Design and Architecture stage triggered by Software Feature Design trigger.	Typically done manually by internal or independent assessors.

Table 44 Reference Model Requirements - IaaS Security, Design and Architecture Stage

Secure Code Stage Requirements

Ref #	sub-category	Description	Notes
2.4.9.6.2 sec.code.002	laaC	SCA – Software Composition Analysis should be applied during Secure Coding stage triggered by Pull, Clone or Comment trigger. Security testing that analyses application source code or compiled code for software components with known vulnerabilities.	Example: open source OWASP range of tools.
sec.code.003	laaC	Source Code Review should be performed continuously during Secure Coding stage.	Typically done manually.
sec.code.004	laaC	Integrated SAST via IDE Plugins should be used during Secure Coding stage triggered by Developer Code trigger. On the local machine: through the IDE or integrated test suites; triggered on completion of coding by developer.	
sec.code.005	laaC	SAST of Source Code Repo should be performed during Secure Coding stage triggered by Developer Code trigger. Continuous delivery pre-deployment: scanning prior to deployment.	

2.4.9.6.3 **Table 45 Reference Model Requirements - IaaS Security, Secure Code Stage**

Continuous Build, Integration and Testing Stage Requirements

Ref #	sub-category	Description	Notes
sec.bld.001	laaC	SAST -Static Application Security Testing should be applied during the Continuous Build, Integration and Testing stage triggered by Build and Integrate trigger.	Example: open source OWASP range of tools.
sec.bld.002	laaC	SCA – Software Composition Analysis should be applied during the Continuous Build, Integration and Testing stage triggered by Build and Integrate trigger.	Example: open source OWASP range of tools.

Ref #	sub-category	Description	Notes
sec.bld.004	laaC	DAST – Dynamic Application Security Testing should be applied during the Continuous Build, Integration and Testing stage triggered by Stage & Test trigger. Security testing that analyses a running application by exercising application functionality and detecting vulnerabilities based on application behavior and response.	Example: OWASP ZAP.
sec.bld.005	laaC	Fuzzing should be applied during the Continuous Build, Integration and testing stage triggered by Stage & Test trigger. Fuzzing or fuzz testing is an automated software testing technique that involves providing invalid, unexpected, or random data as inputs to a computer program.	Example: GitLab Open Sources Protocol Fuzzer Community Edition.
sec.bld.006	laaC	IAST – Interactive Application Security Testing should be applied during the Continuous Build, Integration and Testing stage triggered by Stage & Test trigger. Software component deployed with an application that assesses application behavior and detects presence of vulnerabilities on an application being exercised in realistic testing scenarios.	Example: Contrast Community Edition.

2.4.9.6.4 Table 46 Reference Model Requirements - IaaS Security, Continuous Build, Integration and Testing Stage

Continuous Delivery and Deployment Stage Requirements

Ref #	sub-category	Description	Notes
sec.del.003	laaC	Artifact and Image Repository Scan should be continuously applied during the Continuous Delivery and Deployment stage.	Example: GitLab uses the open-source Clair engine for container scanning.

Table 47 Reference Model Requirements - IaaS Security, Continuous Delivery and Deployment Stage

Runtime Defense and Monitoring Requirements

Ref #	sub-category	Description	Notes
2.4.9.6.5 sec.run.002	laaC	RASP – Runtime Application Self-Protection should be continuously applied during the Runtime Defense and Monitoring stage. Security technology deployed within the target application in production for detecting, alerting, and blocking attacks.	
sec.run.003	laaC	Application testing and Fuzzing should be continuously applied during the Runtime Defense and Monitoring stage. Fuzzing or fuzz testing is an automated software testing technique that involves providing invalid, unexpected, or random data as inputs to a computer program.	Example: GitLab Open Sources Protocol Fuzzer Community Edition.
sec.run.004	laaC	Penetration Testing should be continuously applied during the Runtime Defense and Monitoring stage.	Typically done manually.

Table 48 Reference Model Requirements - laaC Security, Runtime Defence and Monitoring Stage

2.4.9.7 Compliance with Standards (source NG126 7.9.10 0)

Ref #	sub-category	Description	Notes
sec.std.001	Standards	The Cloud Operator should comply with Center for Internet Security CIS Controls Error! Reference source not found.	
sec.std.002	Standards	The Cloud Operator, Platform and Workloads should follow the guidance in the CSA Security Guidance for Critical Areas of Focus in Cloud Computing (latest version) Error! Reference source not found.	
sec.std.003	Standards	The Platform and Workloads should follow the guidance in the OWASP Cheat Sheet Series (OCSS) Error! Reference source not found.	

Ref #	sub-category	Description	Notes
sec.std.004	Standards	The Cloud Operator, Platform and Workloads should ensure that their code is not vulnerable to the OWASP Top Ten Security Risks Error! Reference source not found.	
sec.std.005	Standards	The Cloud Operator, Platform and Workloads should strive to improve their maturity on the OWASP Software Maturity Model (SAMM) Error! Reference source not found.	
sec.std.006	Standards	The Cloud Operator, Platform and Workloads should utilize the OWASP Web Security Testing Guide Error! Reference source not found.	
sec.std.007	Standards	The Cloud Operator, and Platform should satisfy the requirements for Information Management Systems specified in ISO/IEC 27001 0; ISO/IEC 27001 is the international Standard for best-practice information security management systems (ISMSs)	
sec.std.008	Standards	The Cloud Operator, and Platform should implement the Code of practice for Security Controls specified ISO/IEC 27002:2013 (or latest) 0	
sec.std.009	Standards	The Cloud Operator, and Platform should implement the ISO/IEC 27032:2012 (or latest) Guidelines for Cybersecurity techniques 0; ISO/IEC 27032 is the international Standard focusing explicitly on cybersecurity.

Table 49 Security Recommendations

3 Cloud Infrastructure Architecture - OpenStack

3.1 Introduction

This Reference Architecture (RA-1) aims to provide an OpenStack distribution agnostic reference architecture that includes the Network Function Virtualisation Infrastructure (NFVI) and Virtual Infrastructure Manager (VIM). The different OpenStack distributions, without the not up-streamed vendor specific enhancements, are assumed to be conformant. This Reference Architecture allows operators to provide a common OpenStack-based architecture for any compliant VNF to be deployed and operated as expected. The purpose of this section is to outline all the components required to provide the Cloud Infrastructure (NFVI and the VIM) in a consistent and reliable way.

OpenStack **Error! Reference source not found.** is already very well documented and, hence, this document will describe the specific OpenStack services and features, Cloud Infrastructure features and how we expect them to be implemented.

This reference architecture provides optionality in terms of pluggable components such as SDN, hardware acceleration and support tools.

The Cloud Infrastructure layer includes the physical infrastructure which is then offered as virtual resources via a hypervisor. The VIM is the OpenStack OpenInfra Foundation Train release.

This section is organized as follows:

1. Consumable Infrastructure Resources and Services: these are infrastructure services and resources being exposed northbound for consumption

Multi-tenancy with quotas

- Virtual compute: vCPU / vRAM
- Virtual storage: Ephemeral, Persistent and Image
- Virtual networking – neutron standalone: network plugin, virtual switch, accelerator features
- Virtual networking – 3rd party SDN solution
- Additional network services: Firewall, DC Gateway

Cloud Infrastructure Management Software (VIM): is how we manage the Consumable Infrastructure Resources and Services

1. VIM Core services (keystone, cinder, nova, neutron etc.)

2. Tenant Separation
3. Host aggregates providing resource pooling
4. Flavour*¹ management

Underlying Resources: are the resources that allow the Consumable Infrastructure Resources and Services to be created and managed by the Cloud Infrastructure Management Software (VIM).

1. Virtualisation
2. Physical infrastructure
 - a) Compute
 - b) Network: Spine/Leaf; East/West and North/South traffic
 - c) Storage

3.2 Consumable Infrastructure Resources and Services

This section describes the different services that are exposed for the VNF consumption within the execution zone:

1. Tenants: to provide isolated environments
2. Virtual Compute: to provide computing resources
3. Virtual Storage: to provide storage capacity and performance
4. Virtual networking: to provide connectivity within the Cloud Infrastructure and with external networks

3.2.1 Multi-Tenancy (execution environment)

The multi tenancy service permits hosting of several VNF projects with the assurance of isolated environments for each project. Tenants or confusingly "Projects" in OpenStack are isolated environments that enable workloads to be logically separated from each other with:

1. differentiated set of associated users
2. role-based access of two levels – admin or member (see RBAC security section 6.3.2.5).
3. quota system to provide maximum resources that can be consumed.

This RA does not intend to restrict how workloads are distributed across tenants.

3.2.2 Virtual Compute (vCPU and vRAM)

The virtual compute resources (vCPU and vRAM) used by the VNFs behave like their physical counterparts. A physical core is an actual processor and can support multiple vCPUs through Simultaneous Multithreading (SMT) and CPU overbooking. With no overbooking and SMT of 2 (2 threads per core), each core can support 2 vCPUs. With the same SMT of 2 and overbooking factor of 4, each core can support 8 vCPUs. The

¹ Please note "flavours" is used in the Reference Model and shall continue to be used in the context of specifying the geometry of the virtual resources. The term "flavour" is used in this document in the OpenStack context including when specifying configurations; the OpenStack term flavour includes the profile configuration information as "extra specs".

performance of a vCPU can be affected by various configurations such as CPU pinning, NUMA alignment, and SMT.

The configuration of the virtual resources will depend on the software and hardware profiles and the flavour (resource sizing) needed to host VNF components. Profiles are defined in the Reference Model section 2.5.0 and discussed later in Section 4.2.2.5.

3.2.3 Virtual Storage

The three storage services offered by Cloud Infrastructure are:

1. Persistent storage
2. Ephemeral storage
3. Image storage

Two types of persistent data storage are supported in OpenStack:

1. Block storage
2. Object storage

The OpenStack services, Cinder for block storage and Swift for Object Storage, are discussed below in Section 3.3 "Cloud Infrastructure Management Software (VIM)".

Ephemeral data is typically stored on the compute host's local disks, except in environments that support live instance migration between compute hosts. In the latter case, the ephemeral data would need to be stored in a storage system shared between the compute hosts such as on persistent block or object storage.

Images are stored using the OpenStack Glance service discussed below in Section 3.3 "Cloud Infrastructure Management Software (VIM)".

The OpenStack Storage Table **Error! Reference source not found.** explains the differences between the storage types and typical use cases. The OpenStack compatible storage backend drivers **Error! Reference source not found.** table lists the capabilities that each of these drivers support.

3.2.4 Virtual Networking Neutron standalone

Neutron is an OpenStack project that provides "network connectivity as a service" between interface devices (e.g., vNICs) managed by other OpenStack services (e.g., Nova). Neutron allows users to create networks, subnets, ports, routers etc. Neutron also facilitates traffic isolation between different subnets - within as well as across project(s) by using different type driver's/mechanism drivers that use VLANs, VxLANs, GRE (Generic Routing Encapsulation) tunnels etc. For Neutron API consumer, this is abstracted and provided by Neutron. Multiple network segments are supported by Neutron via ML2 plugins to simultaneously utilize variety of layer 2 networking technologies like VLAN, VxLAN, GRE etc. Neutron also allows to create routers to connect layer 2 networks via "neutron-l3-agent". In addition, floating IP support is also provided that allows a project VM to be accessed using a public IP.

3.2.5 Virtual Networking – 3rd party SDN solution

SDN (Software Defined Networking) controllers' separate control and data (user) plane functions where the control plane programmatically configures and controls all network data path elements via open APIs. Open Networking Forum (ONF) defines SDN as "Software-Defined Networking (SDN) is an emerging architecture that is dynamic, manageable, cost-effective, and adaptable, making it ideal for the high-bandwidth, dynamic nature of today's applications. This architecture decouples the network control and forwarding functions enabling the network control to become directly programmable and the underlying infrastructure to be abstracted for applications and network services."

The key messages of the SDN definition are:

1. Decoupling of control and forwarding functions into control plane and data plane
2. Networking capabilities that can be instantiated, deployed, configured and managed like software. Network control is programmable and supports dynamic, manageable and adaptable networking.
3. Support for both overlay and underlay networking

OpenStack Neutron supports open APIs and a pluggable backend where different plugins can be incorporated in the neutron-server.

Plugins for various SDN controllers include either the standard ML-2 plugin or specific monolithic plugins. Neutron supports both core plugins that deal with L2 connectivity and IP address management, and service plugins that support services such as L3 routing, Load Balancers, Firewalls, etc.

Below we will explore an example of an SDN controller from LFN projects, that can be integrated with a Neutron plugin, to help overcome a number of shortcomings of the vanilla Neutron and provide many needed features that can be consumed by VNF/CNF.

3.2.6 Tungsten Fabric (SDN Controller)

Tungsten Fabric **Error! Reference source not found.**, an open source SDN in Linux Foundation Networking, offers neutron networking through ML2 based plugin, additionally it supports advanced networking features beyond basic neutron networking via monolithic plugin. It also supports the same advanced networking features via CNI plugin in Kubernetes. Hence, it works as a multi-stack SDN to support VMs, containers, and bare metal workloads. It provides separation of control plane functions and data plane functions with its two components:

1. Tungsten Fabric Controller– a set of software services that maintains a model of networks and network policies, typically running on several servers for high availability
2. Tungsten Fabric vRouter– installed in each host that runs workloads (virtual machines or containers), the vRouter performs packet forwarding and enforces network and security policies

It is based on proven, standards-based networking technologies but repurposed to work with virtualised workloads and cloud automation in data centres that can range from large scale enterprise data centres to much smaller telco DC (aka POPs). It provides many enhanced features over the native networking implementations of orchestrators, including:

1. Highly scalable, multi-tenant networking
2. Multi-tenant IP address management
3. DHCP, ARP proxies to avoid flooding into networks
4. Efficient edge replication for broadcast and multicast traffic
5. Local, per-tenant DNS resolution
6. Distributed firewall with access control lists
7. Application-based security policies

8. Distributed load balancing across hosts
9. Network address translation (1:1 floating IPs and distributed SNAT)
10. Service chaining with virtual network functions
11. Dual stack IPv4 and IPv6
12. BGP peering with gateway routers
13. BGP as a Service (BGPaaS) for distribution of routes between privately managed customer networks and service provider networks

Based on the network layering concepts introduced in the Reference Model Section 3.5 0, the Tungsten Fabric Controller performs functions of both the SDN underlay (SDNu) and overlay (SDNo) controllers.

The SDN controller exposes a NB API that can be consumed by ETSI MANO for VNF/CNF on boarding, network service on boarding and dynamic service function chaining.

3.2.7 Acceleration

Acceleration deals with both hardware and software accelerations. Hardware acceleration is the use of specialised hardware to perform some function faster than is possible by executing the same function on a general-purpose CPU or on a traditional networking (or other I/O) device (e.g., NIC, switch, storage controller, etc.). The hardware accelerator covers the options for ASICs, SmartNIC, FPGAs, GPU etc. to offload the main CPU, and to accelerate workload performance. Cloud Infrastructure should manage the accelerators by plugins and provide the acceleration capabilities to VNFs.

With the acceleration abstraction layer defined, hardware accelerators as well as software accelerators can be abstracted as a set of acceleration functions (or acceleration capabilities) which exposes a common API to either the VNF or the host.

3.3 Virtualised Infrastructure Manager (VIM)

The Cloud Infrastructure Management Software (VIM) provides the services for the management of Consumable Resources/Services.

3.3.1 VIM Core services

OpenStack is a complex, multi-project framework, and so we will initially focus on the core services required to provide Infrastructure-as-a-Service (IaaS) as this is generally all that is required for Cloud Infrastructure/VIM use cases. Other components are optional and provide functionality above and beyond Cloud Infrastructure/VIM requirements.

The architecture consists of the core services shown in the **Error! Reference source not found.**; Ironic is an optional OpenStack service needed only for bare-metal containers. The rest of this document will address the specific conformant implementation requirements and recommendations for the core services.

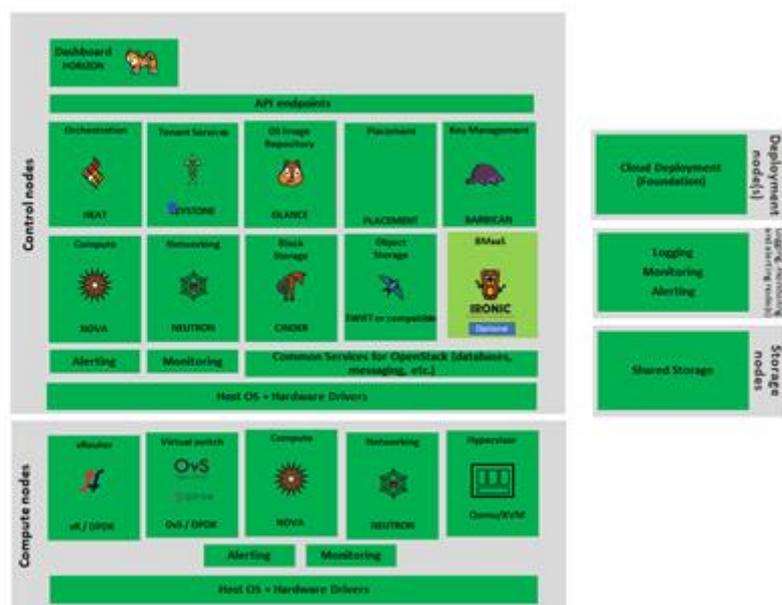

Figure 1 OpenStack Core Services

We will refer to the functions above as falling into the following categories to avoid any confusion with other terminology that may be used:

3. Foundation node
4. Control nodes
5. Compute nodes
6. Other supporting service nodes e.g., network, shared storage, logging, monitoring and alerting.

Each deployment of OpenStack should be a unique cloud with its own API endpoint. Sharing underlying cloud resources across OpenStack clouds is not recommended.

3.3.1.1 OpenStack Services Topology

OpenStack software services are distributed over 2 planes:

1. Control Plane that hosts all Control and Management services
2. Data Plane (a.k.a. User plane) that provides physical and virtual resources (compute, storage, and networking) for the actual virtual workloads to run.

The architecture based on OpenStack technology relies on different types of nodes associated with specific roles:

1. Controller node types with control and management services, which include VIM functionalities
2. Compute node types running workloads
3. Network node types offering L3 connectivity
4. Storage node types offering external attached storage (block, object, flat files)

The data plane consists of the compute nodes. It is typical to consider the other node types to be part of the control plane. **Error! Reference source not found.** depicts the 4 types of nodes constitutive of the Infrastructure: control, compute, network, and storage nodes.

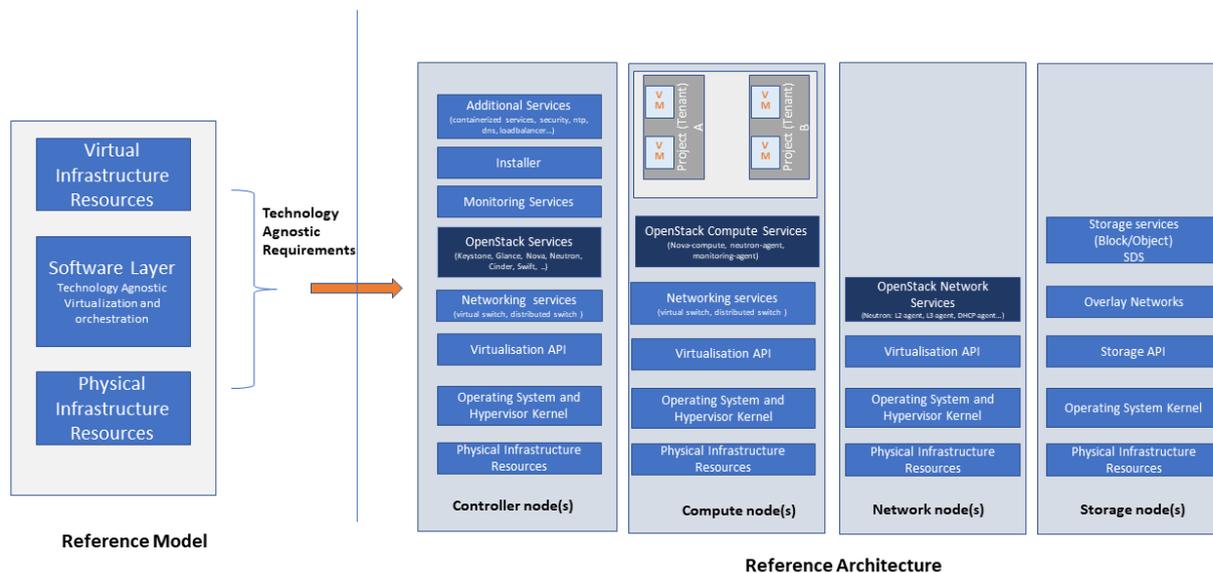

Figure 2 OpenStack Services Topology

Deployments can be structured using the distribution of services amongst the 4 node types as depicted in **Error! Reference source not found.**, but depending on workloads requirements, OpenStack services can also be hosted on the same nodes. For instance, services related to Controller, network and storage roles can all be hosted on controller nodes.

3.3.1.2 Foundation Services

To build and lifecycle manage an OpenStack cloud, it is typically necessary to deploy a server or virtual machine as a deployment node or foundation node.

This function must be able to manage the bare-metal provisioning of the hardware resources but since this does not affect cloud execution it can be detached from the OpenStack cloud and an operator can select their own tooling as they wish. Functional requirements of this node include:

1. Build the cloud (control, compute, storage, network hardware resources)
2. Patch management / upgrades / change management
3. Grow / Shrink resources

3.3.1.3 Cloud Controller Services

The following OpenStack components are deployed on the Infrastructure. Some of them will be only deployed on control hosts and some of them will be deployed within both control and compute hosts. The Table also maps the OpenStack core services to the Reference Model

(RM) Virtual Infrastructure Manager Reference Model section 3.2.2 Virtual Infrastructure Manager 0.

RM Management Software	Service	Description	Required / Optional	Deployed on Controller Nodes	Deployed on Compute Nodes
Identity Management (Additional Management Functions) + Catalogue	Keystone	the authentication service	Required	X	
Storage Resources Manager	Glance	the image management service	Required	X	
Storage Resources Manager	Cinder	the block storage management service	Required	X	
Storage Resources Manager	Swift	the Object storage management service	Required	X	
Network Resources Manager	Neutron	the network management service	Required	X	X
Compute Resources Inventory	Placement	resource provider inventory service	Required	X	
Compute Resources Manager + Scheduler	Nova	the compute resources management service	Required	X	X
Compute Resources Manager	Ironic	the Bare Metal Provisioning service	Optional	X	X
(Tool that utilizes APIs)	Heat	the orchestration service	Required	X	
UI	Horizon	the WEB UI service	Required	X	

RM Management Software	Service	Description	Required / Optional	Deployed on Controller Nodes	Deployed on Compute Nodes
Key Manager	Barbican	the secret data management service	Optional	X	

Table 50 Cloud Controller Services

All components must be deployed within a high available architecture that can withstand at least a single node failure and respects the anti-affinity rules for the location of the services (i.e., instances of the same service must run on different nodes).

The services can be container or VM hosted as long as they satisfy the high availability principles described above.

The APIs for these OpenStack services are listed in section “Interfaces and APIs”.

3.3.1.4 Cloud Workload Services

This section describes the core set of services and service components needed to run workloads; instances (such as VMs), their networks and storage are referred to as the “Compute Node Services” (a.k.a. user or data plane services). Contrast this with the Controller nodes which host OpenStack services used for cloud administration and management. The Compute Node Services include virtualisation, hypervisor instance creation/deletion, networking and storage services; some of these activities include RabbitMQ queues in the control plane including the scheduling, networking and cinder volume creation/attachment.

1. Compute, Storage, Network services:

- a) Nova Compute service: nova-compute (creating/deleting instances)
- b) Neutron Networking service: neutron-l2-agent (manage local Open vSwitch (OVS) configuration), VXLAN
- c) Local Storage (Ephemeral, Root, etc.)
- d) Attached Storage (using Local drivers)

3.3.2 Tenant Isolation

In Keystone v1 and v2 (both deprecated), the term "tenant" was used in OpenStack. With Keystone v3, the term "project" got adopted and both the terms became interchangeable. According to OpenStack glossary **Error! Reference source not found.**, Projects represent the base unit of resources (compute, storage and network) in OpenStack, in that all assigned resources in OpenStack are owned by a specific project. OpenStack offers multi-tenancy by means of resource (compute, network and storage) separation via projects. OpenStack offers ways to share virtual resources between projects while maintaining logical separation. As an example, traffic separation is provided by creating different VLAN ids for neutron networks of different projects. As another example, if host separation is needed, nova scheduler offers `AggregateMultiTenancyIsolation` scheduler filter to separate projects in host aggregates. Thus, if a host in an aggregate is configured for a particular project, only

the instances from that project are placed on the host. Overall, isolation ensures that the resources of a project are not affected by resources of another project.

This document uses the term "project" when referring to OpenStack services and "tenant" (RM Section 3.2.1 [1]) to represent an independently manageable logical pool of resources.

3.3.3 Cloud partitioning: Host Aggregates, Availability Zones

Cloud administrators can partition the hosts within an OpenStack cloud using Host Aggregates and Availability Zones.

A Host Aggregate is a group of hosts (compute nodes) with specific characteristics and with the same specifications, software and/or hardware properties. Example would be a Host Aggregate created for specific hardware or performance characteristics. The administrator assigns key-value pairs to Host Aggregates, these are then used when scheduling VMs. A host can belong to multiple Host Aggregates. Host Aggregates are not explicitly exposed to tenants.

Availability Zones (AZs) rely on Host Aggregates and make the partitioning visible to tenants. They are defined by attaching specific metadata information to an aggregate, making the aggregate visible for tenants. Hosts can only be in a single Availability Zone. By default, a host is part of a default Availability Zone, even if it doesn't belong to an aggregate. Availability Zones can be used to provide resiliency and fault tolerance for workloads deployments, for example by means of physical hosting distribution of Compute Nodes in separate racks with separate power supply and eventually in different rooms. They permit rolling upgrades – an AZ at a time upgrade with enough time between AZ upgrades to allow recovery of tenant workloads on the upgraded AZ. AZs can also be used to segregate workloads.

An overuse of Host Aggregates and Availability Zones can result in a granular partition of the cloud and, hence, operational complexities and inefficiencies.

3.3.4 Flavour management

In OpenStack a flavour defines the compute, memory, and storage capacity of nova instances. When instances are spawned, they are mapped to flavours which define the available hardware configuration for them. For simplicity, operators may create named flavours specifying both the sizing and the software and hardware profile configurations (RM Section 5 0).

3.4 Underlying Resources

The number of compute nodes (for workloads) determine the load on the controller nodes and networking traffic and, hence, the number of controller nodes needed in the OpenStack cloud; the number of controller nodes required is determined on the load placed on these controller nodes and the need for High availability and quorum requires at least 3 instances of many of the services on these controller nodes.

3.4.1 Virtualisation

Virtualisation is a technology that enables a guest Operating System (OS) to be abstracted from the underlying hardware and software. This allows to run multiple Virtual Machines

(VMs) on the same hardware. Each such VMs have their own OS and are isolated from each other i.e., application running on one VM does not have the access to resources of another VM. Such virtualisation is supported by various hypervisors available as open source (KVM, Xen etc.) as well as commercial (Hyper-V, Citrix XenServer etc.). Selecting a hypervisor depends on the workload needs and the features provided by various hypervisors as illustrated in Hypervisor Feature Support Matrix **Error! Reference source not found.** OpenStack (Nova) allows the use of various hypervisors within a single installation by means of scheduler filters like ComputeFilter, ImagePropertiesFilter etc.

Virtualisation Services: The OpenStack nova-compute service supports multiple hypervisors natively or through libvirt. The preferred supported hypervisor in this Reference Architecture is KVM.

Note: Other hypervisors (such as ESXi) can also be supported if they can interoperate with OpenStack components (e.g., those listed in this Reference Architecture) using standard interfaces and APIs as specified in Section 5.

3.4.2 Physical Infrastructure

The aim is to specify the requirements on deploying the VIM, from ground up (in a shipping container), and what resources are required of the DC (Data Centre).

1. Servers
 - a. Compute
 - b. Storage
 - c. Control (min 3 for Core DC)
2. Network considerations
 - a. Data centre gateway
 - b. Firewall (around the control plane, storage, etc.)
 - c. Data centre network fabric / Clos (spine/leaf) – Horizontal scale
 - d. Storage networking, control plane and data plane
 - e. Raw packet – tenant networking allowing “wild west” connection.
3. Storage
 - a. discussed in section 4.2.4
4. Acceleration
 - a. SmartNIC
 - b. GPU
 - c. FPGA

3.4.2.1 Compute

Cloud Infrastructure Physical Nodes

The physical resources required for the Cloud Infrastructure are mainly based on COTS x86 hardware for control and data plane nodes. HW profiles are defined in Reference Model sections 5.3 and 5.4 0.

Network

The recommended network architecture is spine and leaf topology.

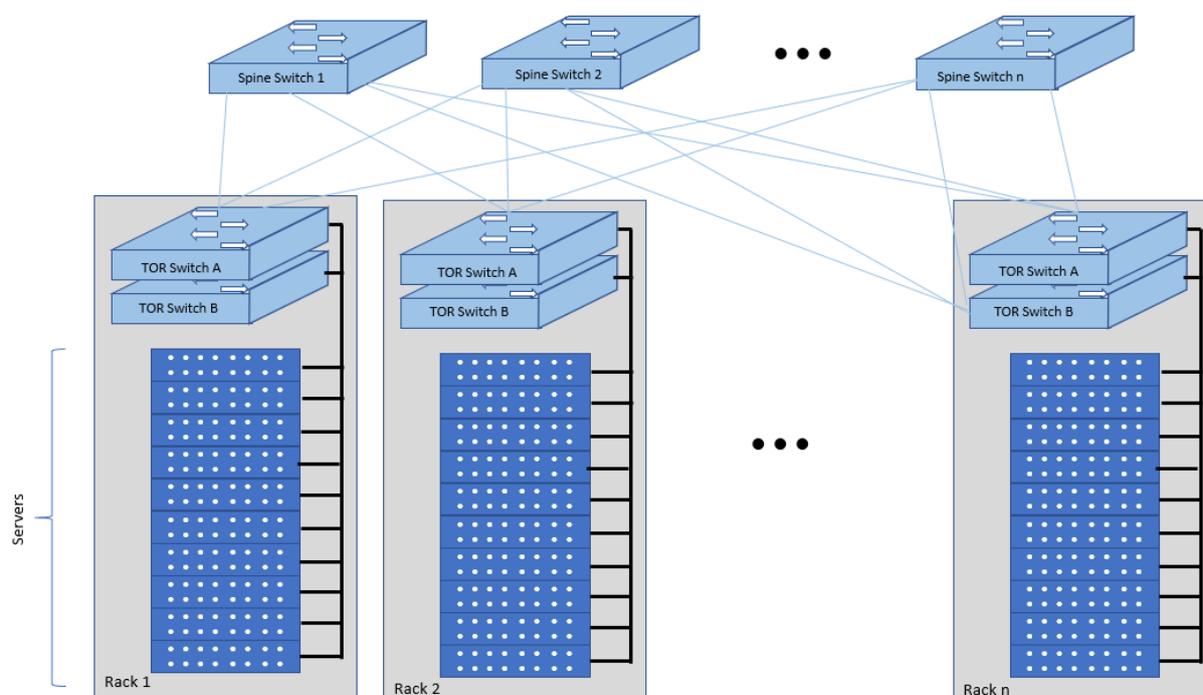

Figure 3 Network Fabric – Physical

Error! Reference source not found. shows a physical network layout where each physical server is dual homed to TOR (Leaf/Access) switches with redundant (2x) connections. The Leaf switches are dual homed with redundant connections to spines.

3.4.2.2 Storage

OpenStack Storage **Error! Reference source not found.** supports many different storage architectures and backends. The choice of a particular backend storage is driven by several factors including scalability, resiliency, availability, data durability, capacity, and performance.

Most cloud storage architectures incorporate a number of clustered storage nodes that provide high bandwidth access to physical storage backends connected by high-speed networks. The architecture consists of multiple storage controller units, each a generic server (CPU, Cache, storage), managing a number of high-performance hard drives. The distributed block storage software creates an abstract single pool of storage by aggregating all of the controller units. Advanced and high-speed networking (data routing) and global load balancing techniques ensure high performance, high availability storage system.

3.5 Cloud Topology

A telco cloud will typically be deployed in multiple locations (“sites”) of varying size and capabilities (HVAC, for example); or looking at this in the context of OpenStack, multiple clouds (i.e., OpenStack endpoints) will be deployed that do not rely on each other by design; each cloud consists of a set of resources isolated from resources of the other clouds. The application layer must span such endpoints to provide the required service SLA. Irrespective of the nature of the deployment characteristics (e.g., number of racks, number of hosts, etc.), the intent of the architecture should be to allow VNFs to be deployed in these sites without major changes.

Some examples of such topologies include:

1. Large data centre capable of hosting potentially thousands of servers and the networking to support them
2. Intermediate data centre (such as a central office) capable of hosting up to a hundred servers
3. Edge (not customer premise) capable of hosting ten to fifty servers

In order to provide the expected availability for any given service, a number of different OpenStack deployment topologies can be considered. This section explores the main options and highlights the characteristics of each. Ultimately the decision rests with the operator to achieve specific availability target taking into account use cases, data centre capabilities, economics and risks.

Availability of any single OpenStack cloud is dependent on a number of factors including:

1. environmental – dual connected power and PDUs, redundant cooling, rack distribution etc.
2. resilient network fabric – ToR (leaf), spine, overlay networking, underlay networking etc. It is assumed that all network components are designed to be fault tolerant and all OpenStack controllers, computes and storage are dual homed to alternate leaf switches.
3. controller nodes setup in-line with the vendor recommendation (e.g., min 3 physical nodes)
4. network nodes (where applicable)
5. backend storage nodes setup for high availability based on quorum (aligned with vendor implementation)
6. compute nodes sized to handle the entire workload following local failure scenario

3.5.1 Topology Overview

Assumptions and conventions:

1. Region is represented by a single OpenStack control plane.
2. Resource Failure Domain is effectively the “blast radius” of any major infrastructure failure such as loss of PDU or network leafs.
3. Control plane includes redundant network nodes where OVS-kernel is used.
4. Controller nodes should be setup for high availability based on quorum (aligned with vendor implementation).

5. Shared storage is optional, but it is important to ensure shared assets are distributed across serving clouds such as boot images.

Topology Ref	Type	Control Planes	Shared Storage (optional)	Compute Azs	Achievable Service Availability %	Service Multi-region awareness	Notes
1	Local Redundancy – workload spread across servers	1	1	1	Variable	Not required	Suitable where only limited local application availability is required e.g. nova anti-affinity
2	Regional Redundancy – workload spread across Azs	1	>=2	>=2	>99.n	Not required	Suitable where local application HA is required. Control plane should be distributed across DC failure domains (assuming layer 2 connectivity) but may be unavailable during upgrades
3	Global Redundancy – workload spread across multiple Regions	>=2	>=2	>=2	>99.nn	Required	Suitable where local and region application HA is required Control plane could be kept available in one site during upgrades

Table 51 Topology overview

3.5.2 Topology Detail

3.5.2.1 Topology 1 - Local Redundancy

Under normal operation this deployment can handle a single failure of a controller node or storage node without any impact to the service. If a compute node fails, the application layer (often the VNFM) would need to restart workloads on a spare compute node of similar capability i.e., cloud may need to be provided with n+1 capacity. In the case of an active/active application deployed to separate compute nodes (with hypervisor anti-affinity) there would be no service impact.

Important to consider:

1. Where possible servers should be distributed and cabled to reduce the impact of any failure e.g., PDU, rack failure. Because each operator has individual site constraints this document will not propose a standard rack layout.
2. During maintenance of the control plane, whilst the data (forwarding) plane remains unaffected, the control plane API may not be available, and some applications may be relying on it during normal application operation for example for scaling. Additionally, if the upgrade involves updating OpenStack services on the compute nodes care needs to be taken. OVS-kernel networking operations may also be impacted during this time.
3. During maintenance of storage (e.g., ceph) there is an increased risk of a service-impacting failure and so it is generally recommended to deploy at least one more server than the minimum required for redundancy.

3.5.2.2 Topology 2 - Regional Redundancy

Under normal operation this topology can handle a single failure of a controller node but provides additional protection to the compute plane and storage. If the application is deployed across 2 or more AZs a major failure impacting the nodes in one AZ can be tolerated assuming the application deployment allows for this. There is a risk with split-brain so a means of deciding application quorum is recommended or by using a third AZ or arbitrator.

Important to consider:

1. All those points listed for Topology 1 above.
2. When using 3 controller nodes and distributing these physically across the same locations as the computes, if you lose the location with 2 controllers the OpenStack services would be impacted as quorum cannot be gained with a single controller node. It is also possible to use more than 3 controller nodes and co-locate one with each compute AZ allowing lower-risk maintenance, but care must be taken to avoid split brain.
3. The distributed network fabric must support L2 for the OpenStack control plane VIPs.

3.5.2.3 Topology 3 - Global Redundancy

Following the example set by public cloud providers who provide Regions and Availability Zones this is effectively a multi-region OpenStack. Assuming the application can make use of this model, this topology provides the highest level of availability but would require IP level failure to be controlled outside of OpenStack by global service load balancing (GSLB), i.e.,

DNS with minimum TTL configured, or client applications that are capable of failing over themselves. This topology has the added advantage that no resources are shared between different Regions and so any fault is isolated to a single cloud, and also allows maintenance to take place without service impact.

4 Cloud Infrastructure + VIM Component Level Architecture

4.1 Introduction

Section 3 introduced the components of an OpenStack-based IaaS

1. Consumable Infrastructure Resources and Services
2. Cloud Infrastructure Management Software (VIM: OpenStack) core services and architectural constructs needed to consume and manage the consumable resources
3. Underlying physical compute, storage and networking resources

This section delves deeper into the capabilities of these different resources and their needed configurations to create and operate an OpenStack-based IaaS cloud. This section specifies details on the structure of control and user planes, operating systems, hypervisors and BIOS configurations, and architectural details of underlay and overlay networking, and storage, and the distribution of OpenStack service components among nodes. The section also covers implementation support for the Reference Model profiles and flavours (RM Section 2.4.0); the OpenStack flavour types capture both the sizing and the profile configuration (of the host).

4.2 Underlying Resources

4.2.1 Virtualisation

In OpenStack, KVM is configured as the default hypervisor for compute nodes.

1. Configuration: OpenStack **Error! Reference source not found.** specifies the following KVM configuration steps/instructions to configure KVM:
 - a) Enable KVM based hardware virtualisation in BIOS. OpenStack provides instructions on how to enable hardware virtualisation for different hardware platforms (x86, Power)
 - b) QEMU is similar to KVM in that both are libvirt controlled, have the same feature set and utilise compatible virtual machine images
 - c) Configure Compute backing storage
2. DSpecify the CPU Model for KVM guests (VMs)
3. EKVM Performance Tweaks
4. Hardening the virtualisation layers [Error! Reference source not found.](#)
 - a) OpenStack recommends minimizing the code base by removing unused components
 - b) sVirt (Secure Virtualisation) provides isolation between VM processes, devices, data files and system processes

4.2.2 Compute

4.2.2.1 Cloud Deployment (Foundation/management) Node

Minimal configuration: 1 node

4.2.2.2 OpenStack Control Plane Servers (Control Nodes)

- BIOS Requirements
 - a) For OpenStack control nodes we use the BIOS parameters for the basic profile defined in section 5.4 of the Reference Model 0. Additionally, for OpenStack we need to set the following boot parameters:

BIOS/boot Parameter	Value
Boot disks	RAID 1
CPU reservation for host (kernel)	1 core per NUMA
CPU allocation ratio	2:1

Table 52 BIOS/boot parameters – Control node

- How many nodes to meet SLA
 - a. Minimum 3 nodes for high availability
- HW specifications
 - a. Boot disks are dedicated with Flash technology disks
- Sizing rules
 - a. It is easy to horizontally scale the number of control nodes
 - b. The number of control nodes is determined by a minimum number needed for high availability (viz., 3 nodes) and the extra nodes needed to handle the transaction volumes, in particular, for Messaging service (e.g., RabbitMQ) and Database (e.g., MySQL) to track state.
 - c. The number of control nodes only needs to be increased in environments with a lot of changes, such as a testing lab, or a very large cloud footprint (rule of thumb: number of control nodes = 3 + quotient (number of compute nodes/1000)).
 - d. The Services Placement Summary table **Error! Reference source not found.** specifies the number of instances that are required based upon the cloud size (number of nodes).

4.2.2.3 Network nodes

Network nodes are mainly used for L3 traffic management for overlay tenant network (see more detail in section 4.3.1.5 Neutron).

1. BIOS requirements

BIOS/boot Parameter	Value
Boot disks	RAID 1

Table 53 Boot parameters – Network node

2. How many nodes to meet SLA
 - a) Minimum 2 nodes for high availability using VRRP.
3. 3HW specifications
 - a) 3 NICs card are needed if we want to isolate the different flows:
 - 1 NIC for Tenant Network
 - 1 NIC for External Network
 - 1 NIC for Other Networks (PXE, Mngt ...)
4. Sizing rules
 - a) Scale out of network node is not easy
 - b) DVR can be an option for a large deployment (see more detail in section 4.3.1.5 Neutron)

4.2.2.4 Storage nodes

1. BIOS requirements

BIOS/boot Parameter	Value
Boot disks	RAID 1

Table 54 Boot parameter – Storage node

2. HW specifications: please see NG 126 Section 3.6 0
3. How many nodes to meet SLA: Active-Passive is the default and recently OpenStack started to support Active-Active
4. Sizing rules: minimum 2 x 1 TB; recommended 2 x 10 TB

4.2.2.5 Compute Nodes

This section specifies the compute node configurations to support the Basic and High-Performance profiles; in OpenStack this would be accomplished by specifying the configurations when creating “flavours”. The cloud operator may choose to implement certain profile-extensions (RM 2.4 Profile Extensions 0) as a set of standard configurations, of a given profile, capturing some of the variability through different values or extra specifications.

1. The software and hardware configurations are as specified in the Reference Model section 5.4 0
2. BIOS requirement
 - a) The general BIOS requirements are described in the Reference Model section 5.4 0

Example Profiles and their Extensions

The Reference Model specifies the Basic (B) and High-Performance (H) profile types. The Reference Model also provides a choice of network acceleration capabilities utilising, for example, DPDK and SR-IOV technologies. **Error! Reference source not found.** lists a few simple examples of profile extensions and some of their capabilities.

Profile Extensions	Description	CPU Allocation Ratio	SMT	CPU Pinning	NUMA	Huge Pages	Data Traffic
B1	Basic Profile No CPU over-subscription profile extension	1:1	Y	N	N	N	OVS-kernel

Profile Extensions	Description	CPU Allocation Ratio	SMT	CPU Pinning	NUMA	Huge Pages	Data Traffic
B4	Basic Profile 4x CPU over-subscription profile extension	4:1	Y	N	N	N	OVS-kernel
HV	High Performance Profile	1:1	Y	Y	Y	Y	OVS-kernel
HD	High Performance Profile with DPDK profile extension	1:1	Y	Y	Y	Y	OVS-DPDK
HS	High Performance Profile with SR-IOV profile extension	1:1	Y	Y	Y	Y	SR-IOV

Table 55 Profile Extensions and Capabilities

BIOS Settings

A number of capabilities need to be enabled in the BIOS (such as NUMA and SMT); the Reference Model 0 section 5.1 on “Cloud Infrastructure Software profile description” specifies the capabilities required to be configured. Please note that the required capabilities may need to be configured in multiple systems. For OpenStack, we also need to set the following boot parameters:

BIOS/boot Parameter	Basic	High Performance
Boot disks	RAID 1	RAID 1

Table 56 Boot parameters – Compute node

1. How many nodes to meet SLA
 - a) minimum: two nodes per profile
2. HW specifications
 - a) Boot disks are dedicated with Flash technology disks
3. In case of DPDK usage:

Layer	Description
Cloud infrastructure	Important is placement of NICs to get NUMA-balanced system (balancing the I/O, memory, and storage across both sockets), and configuration of NIC features. Server BIOS and Host OS kernel command line settings are described in “DPDK release notes” Error! Reference source not found. and “DPDK performance reports” Error! Reference source not found. Disabling power settings (like Intel Turbo Boost Technology) brings stable performance results, although understanding if and when they benefit workloads and enabling them can achieve better performance results.
Workload	DPDK uses core affinity along with 1G or 2M Huge Pages, NUMA settings (to avoid crossing interconnect between CPUs), and DPDK Poll Mode Drivers (PMD, on reserved cores) to get the best performance. DPDK versions xx.11 are Long-Term Support maintained stable release with back-ported bug fixes for a two-year period.

Table 57 DPDK configuration**Sizing rules**

Description	Mnemonic
Number of CPU sockets	s
Number of cores	c
SMT	t
RAM	rt
Storage	d
Overcommit	o
Average vCPU per instance	v
Average RAM per instance	ri

Table 58 Sizing values

		Basic	High-Performance
# of VMs per node (vCPU)	$(sct \cdot o) / v$	$4 \cdot (sct) / v$	$(sct) / v$
# of VMs per node (RAM)	rt / ri	rt / ri	rt / ri
Max # of VMs per node		$\min(4 \cdot (sct) / v, rt / ri)$	$\min((sct) / v, rt / ri)$

Table 59 Sizing rules

Caveats:

1. These are theoretical limits
2. Affinity and anti-affinity rules, among other factors, affect the sizing

4.2.2.6 Compute Resource Pooling Considerations

1. Multiple pools of hardware resources where each resource pool caters for workloads of a specific profile (for example, High-Performance) leads to inefficient use of the hardware as the server resources are configured specifically for a profile. If not properly sized or when demand changes, this can lead to oversupply/starvation scenarios; reconfiguration may not be possible because of the underlying hardware or inability to vacate servers for reconfiguration to support another profile type.
2. Single pool of hardware resources including for controllers that have the same CPU configuration. This is operationally efficient as any server can be utilized to support any profile or controller. The single pool is valuable with unpredictable workloads or when the demand of certain profiles is insufficient to justify individual hardware selection.

4.2.2.7 Reservation of Compute Node Cores

The section 2.3.2 “Infrastructure Requirement” `inf.com.08` requires the allocation of “certain number of host cores/threads to non-tenant workloads such as for OpenStack services.” A number (“n”) of random cores can be reserved for host services (including OpenStack services) by specifying the following in nova.conf:

```
reserved_host_cpus = n
```

where n is any positive integer.

If we wish to dedicate specific cores for host processing, we need to consider two different use scenarios:

1. Require dedicated cores for Guest resources
2. No dedicated cores are required for Guest resources

Scenario #1, results in compute nodes that host both pinned and unpinned workloads. In the OpenStack Train release, scenario #1 is not supported; it may also be something that operators may not allow. Scenario #2 is supported through the specification of the `cpu_shared_set` configuration. The cores and their sibling threads dedicated to the host services are those that do not exist in the `cpu_shared_set` configuration.

Let us consider a compute host with 20 cores with SMT enabled (let us disregard NUMA) and the following parameters specified. The physical cores are numbered ‘0’ to ‘19’ while the sibling threads are numbered ‘20’ to ‘39’ where the vCPUs numbered ‘0’ and ‘20’, ‘1’ and ‘21’, etc. are siblings:

```
cpu_shared_set = 1-7,9-19,21-27,29-39    (can also be specified as
cpu_shared_set = 1-19, ^8,21-39, ^28)
```

This implies that the two physical cores '0' and '8' and their sibling threads '20' and '28' are dedicated to the host services, and 19 cores and their sibling threads are available for Guest instances and can be over allocated as per the specified `cpu_allocation_ratio` in `nova.conf`.

4.2.2.8 Pinned and Unpinned CPUs

When a VM instance is created, the vCPUs are, by default, not assigned to a particular host CPU. Certain workloads require real-time or near real-time behaviour viz., uninterrupted access to their cores. For such workloads, CPU pinning allows us to bind an instance's vCPUs to a particular host's cores or SMT threads. To configure a flavour to use pinned vCPUs, we use a dedicated CPU policy.

```
OpenStack flavour set .xlarge --property hw:cpu_policy=dedicated
```

While an instance with pinned CPUs cannot use CPUs of another pinned instance, this does not apply to unpinned instances; an unpinned instance can utilise the pinned CPUs of another instance. To prevent unpinned instances from disrupting pinned instances, the hosts with CPU pinning enabled are pooled in their own host aggregate and hosts with CPU pinning disabled are pooled in another non-overlapping host aggregate.

4.2.2.9 Compute node configurations for Profiles and OpenStack Flavours

This section specifies the compute node configurations to support profiles and flavours.

4.2.2.9.1 Cloud Infrastructure Hardware Profile

The Cloud Infrastructure Hardware (or simply "host") profile and configuration parameters are utilised in the reference architecture to define different hardware profiles; these are used to configure the BIOS settings on a physical server and configure utility software (such as Operating System and Hypervisor).

An OpenStack flavour defines the characteristics ("capabilities") of Virtual Machines (VMs or vServers) that will be deployed on hosts assigned a host-profile. A many to many relationship exists between the flavours and host profiles. Multiple flavours can be defined with overlapping capability specifications with only slight variations such that the VMs of these flavour types can be hosted on similarly configured (host profile) compute hosts. Similarly, a VM can be specified with a flavour that allows it to be hosted on, say, a host configured as per the Basic profile, or a host configured as per the High-Performance profile. Please note that workloads that specify a VM flavour so as to be hosted on a host configured as per the High-Performance profile, may not be able to run (adequately with expected performance) on a host configured as per the Basic profile.

A given host can only be assigned a single host profile; a host profile can be assigned to multiple hosts. Host profiles are immutable and hence when a configuration needs to be changed, a new host profile is created.

CPU Allocation Ratio and CPU Pinning

A given host (compute node) can only support a single CPU Allocation Ratio. Thus, to support the B1 and B4 Basic profile extensions (Section 4.2.2.5) with CPU Allocation Ratios of 1.0 and 4.0 we will need to create 2 different host profiles and separate host aggregates for each of the host profiles. The CPU Allocation Ratio is set in the hypervisor on the host.

When the CPU Allocation Ratio exceeds 1.0 then CPU Pinning also needs to be disabled.

Server Configurations

The different networking choices – OVS-Kernel, OVS-DPDK, SR-IOV – result in different NIC port, LAG (Link Aggregation Group), and other configurations. Some of these are shown diagrammatically in the Section 4.2.9.5.

Leaf and Compute Ports for Server Flavours must align

Compute hosts have varying numbers of Ports/Bonds/LAGs/Trunks/VLANs connected with Leaf ports. Each Leaf port (in A/B pair) must be configured to align with the interfaces required for the compute flavour.

Physical Connections/Cables are generally the same within a zone, regardless of these specific L2/L3/SR-IOV configurations for the compute.

Compute Bond Port: TOR port maps VLANs directly with IRBs on the TOR pair for tunnel packets and Control Plane Control and Storage packets. These packets are then routed on the underlay network GRT.

Server Flavours: B1, B4, HV, HD

Compute SR-IOV Port: TOR port maps VLANs with bridge domains that extend to IRBs, using VXLAN VNI. The TOR port associates each packet's outer VLAN tag with a bridge domain to support VNF interface adjacencies over the local EVPN/MAC bridge domain. This model also applies to direct physical connections with transport elements.

Server Flavours: HS

Notes on SR-IOV

SR-IOV, at the compute server, routes Guest traffic directly with a partitioned NIC card, bypassing the hypervisor and vSwitch software, which provides higher bps/pps throughput for the Guest VM. OpenStack and MANO manage SR-IOV configurations for Tenant VM interfaces.

1. Server, Linux, and NIC card hardware standards include SR-IOV and VF requirements
2. High Performance profile for SR-IOV (hs series) with specific NIC/Leaf port configurations
3. OpenStack supports SR-IOV provisioning
4. Implement Security Policy, Tap/Mirror, QoS, etc. functions in the NIC, Leaf, and other places

Because SR-IOV involves Guest VLANs between the compute server and the ToR/Leafs, Guest automation and VM placement necessarily involves the Leaf switches (e.g., access VLAN outer tag mapping with VXLAN EVPN).

1. Local VXLAN tunnelling over IP-switched fabric implemented between VTEPs on Leaf switches.
2. Leaf configuration controlled by SDN-Fabric/Global Controller.
3. Underlay uses VXLAN-enabled switches for EVPN support

SR-IOV-based networking for Tenant Use Cases is required where vSwitch-based networking throughput is inadequate.

Example Host Configurations

Host configurations for B1, B4 Profile Extensions

4.2

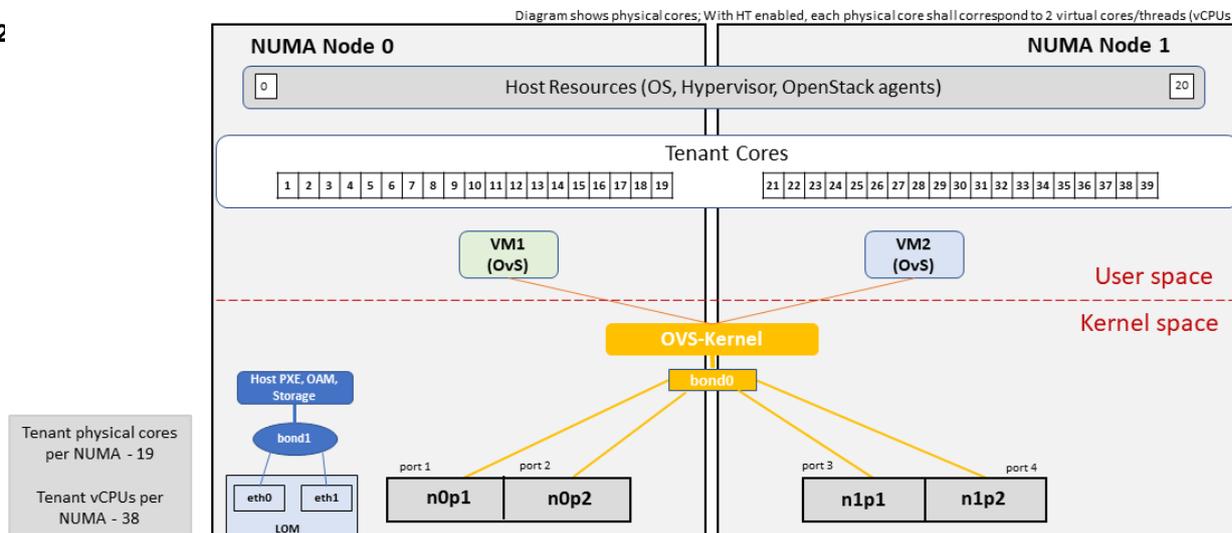

Figure 4 Basic Profile Host Configuration (example and simplified)

Let us refer to the data traffic networking configuration of **Error! Reference source not found.** to be part of the hp-B1-a and hp-B4-a host profiles and this requires the configurations as shown in **Error! Reference source not found.**.

	Configured in	Host profile: hp-B1-a	Host profile: hp-B4-a
CPU Allocation Ratio	Hypervisor	1:1	4:1
CPU Pinning	BIOS	Disable	Disable
SMT	BIOS	Enable	Enable
NUMA	BIOS	Disable	Disable
Huge Pages	BIOS	No	No
Profile Extensions		B1	B4

Table 60 Configuration of Basic Flavour Capabilities

Error! Reference source not found. shows the networking configuration where the storage and OAM share networking but are independent of the PXE network.

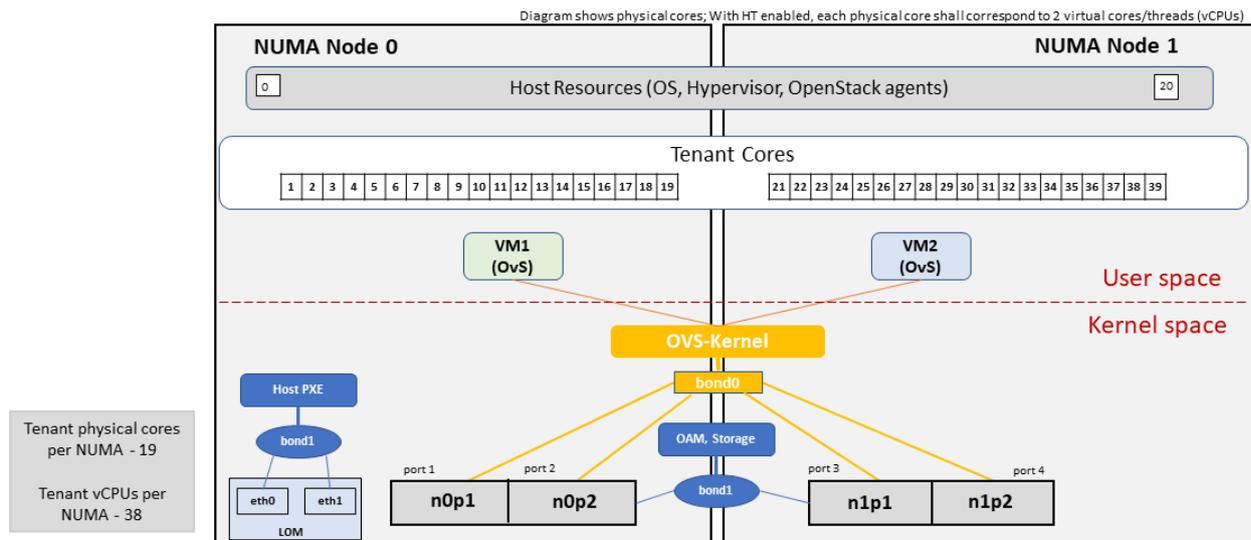

Figure 5 Basic Profile Host Configuration with shared Storage and OAM networking (example and simplified).

Let us refer to the above networking set up to be part of the hp-B1-b and hp-B4-b host profiles, with the basic configurations as specified in **Error! Reference source not found..**

In our example, the Profile Extensions B1 and B4, are each mapped to two different host profiles hp-B1-a and hp-B1-b, and hp-B4-a and hp-B4-b respectively. Different network configurations, reservation of CPU cores, Lag values, etc. result in different host profiles.

To ensure Tenant CPU isolation from the host services (Operating System (OS), hypervisor and OpenStack agents), the following needs to be configured:

GRUB bootloader Parameter	Description	Values
isolcpus (Applicable only on Compute Servers)	A set of cores isolated from the host processes. Contains vCPUs reserved for Tenants	isolcpus=1-19, 21-39, 41-59, 61-79

Table 61 Tenant CPU isolation, Basic profile

Host configuration for HV Profile Extensions

The above examples of host networking configurations for the B1 and B4 Profile Extensions are also suitable for the HV Profile Extensions; however, the hypervisor and BIOS settings will be different (see table below) and hence there will be a need for different host profiles.

Error! Reference source not found. gives examples of three different host profiles: one each for HV, HD and HS Profile Extensions.

	Configured in	Host profile: hp-hv-a	Host profile: hp-hd-a	Host profile: hp-hs-a
Profile Extensions		HV	HD	HS
CPU Allocation Ratio	Hypervisor	1:1	1:1	1:1
NUMA	BIOS, Operating System, Hypervisor and OpenStack Nova Scheduler	Enable	Enable	Enable
CPU Pinning (requires NUMA)	OpenStack Nova Scheduler	Enable	Enable	Enable
SMT	BIOS	Enable	Enable	Enable
Huge Pages	BIOS	Yes	Yes	Yes

Table 62 Configuration of High Performance Flavour Capabilities

Host Networking configuration for HD Profile Extensions

An example of the data traffic configuration for the HD (OVS-DPDK) Profile Extensions is shown in **Error! Reference source not found.**

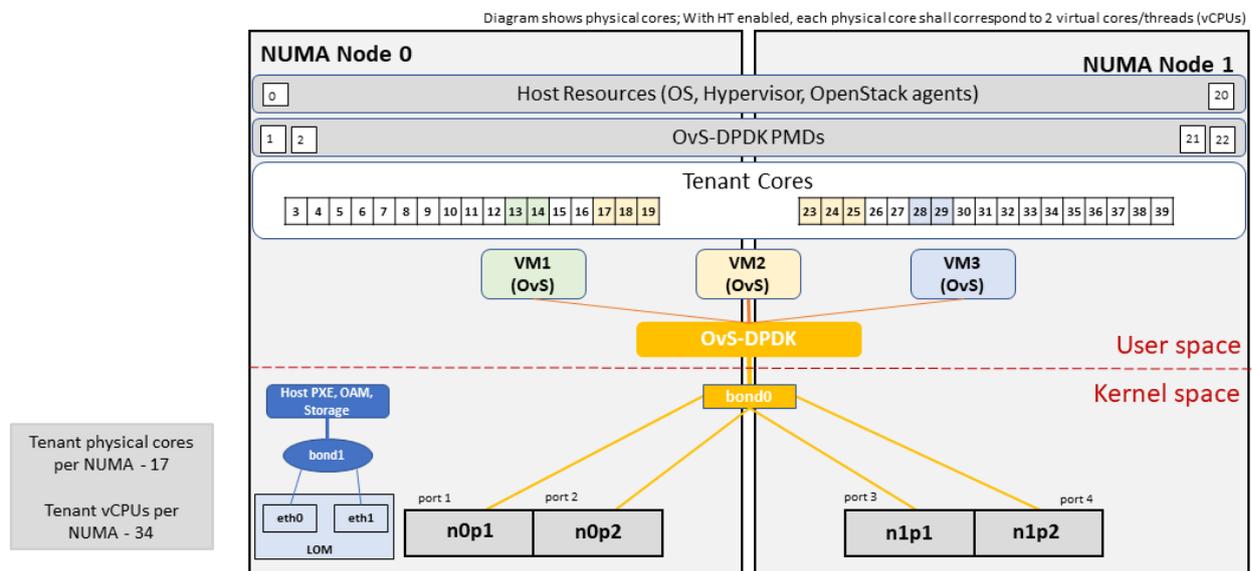

Figure 6 High Performance Profile Host Configuration with DPDK acceleration (example and simplified).

To ensure Tenant and DPDK CPU isolation from the host services (Operating System (OS), hypervisor and OpenStack agents), the following needs to be configured:

Hardening the virtualization layers	Hardening the virtualization layers	Hardening the virtualization layers
isolcpus (Applicable only on Compute Servers)	A set of cores isolated from the host processes. Contains vCPUs reserved for Tenants and DPDK	isolcpus=3-19, 23-39, 43-59, 63-79

Table 63 Tenant and DPDK CPU isolation, HD profile

Host Networking configuration for HS Profile Extensions

An example of the data traffic configuration for the HS (SR-IOV) Profile Extensions is shown in **Error! Reference source not found.**

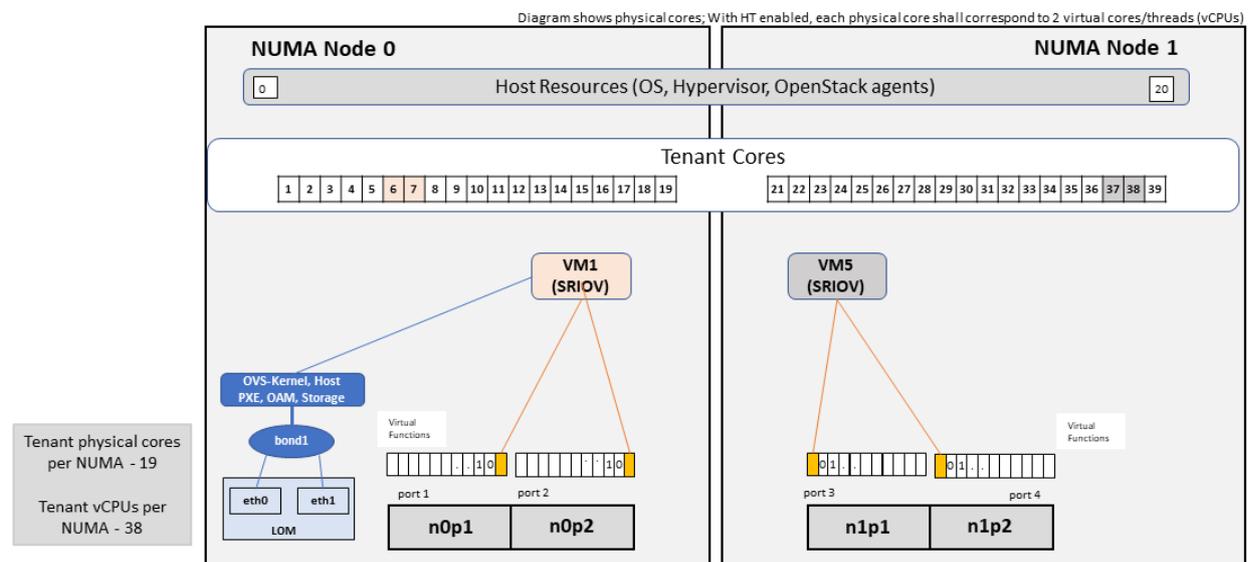

Figure 7 High Performance Profile Host Configuration with SR-IOV (example and simplified).

To ensure Tenant CPU isolation from the host services (Operating System (OS), hypervisor and OpenStack agents), the following needs to be configured (**Error! Reference source not found.**).

GRUB bootloader Parameter	Description	Values
isolcpus (Applicable only on Compute Servers)	A set of cores isolated from the host processes. Contains vCPUs reserved for Tenants	isolcpus=1-19, 21-39, 41-59, 61-79

4.2.2.9.6

Table 64 Tenant CPU isolation, HS profile

Using Hosts of a Host Profile type

As we have seen Profile Extensions are supported by configuring hosts in accordance with the Profile Extensions specifications. For example, an instance of flavour type B1 can be hosted on a compute node that is configured as an hp-B1-a or hp-B1-b host profile. All

compute nodes configured with hp-B1-a or hp-B1-b host profile are made part of a host aggregate, say, ha-B1 and, thus, during VM instantiation of B1 flavour hosts from the ha-B1 host aggregate will be selected.

4.2.3 Network Fabric

Networking Fabric consists of:

1. Physical switches, routers...
2. Switch OS
3. Minimum number of switches
4. Dimensioning for East/West and North/South
5. Spine / Leaf topology – east – west
6. Global Network parameters
7. OpenStack control plane VLAN / VXLAN layout
8. Provider VLANs

4.2.3.1 Physical Network Topology

This section is left blank for future use.

4.2.3.2 High Level Logical Network Layout

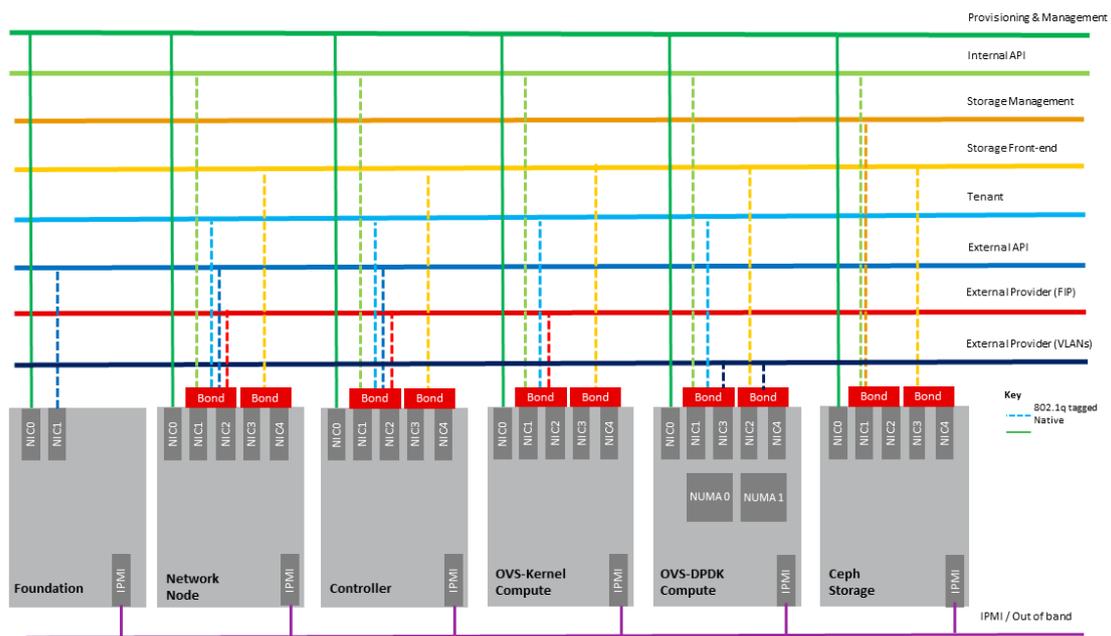

Figure 8 Indicative OpenStack Network Layout.

Network	Description	Characteristics
Provisioning & Management	Initial OS bootstrapping of the servers via PXE, deployment of software and thereafter for access from within the control plane.	Security Domain: Management Externally Routable: No Connected to: All nodes

Network	Description	Characteristics
Internal API	Intra-OpenStack service API communications, messaging and database replication	Security Domain: Management Externally Routable: No Connected to: All nodes except foundation
Storage Management	Backend connectivity between storage nodes for heartbeats, data object replication and synchronization	Security Domain: Storage Externally Routable: No Connected to: All nodes except foundation
Storage Front-end	Block/Object storage access via cinder/swift	Security Domain: Storage Externally Routable: No Connected to: All nodes except foundation
Tenant	VXLAN / Geneve project overlay networks (OVS kernel mode) – i.e., RFC1918 re-usable private networks as controlled by cloud administrator	Security Domain: Underlay Externally Routable: No Connected to: controllers and computes
External API	Hosts the public OpenStack API endpoints including the dashboard (Horizon)	Security Domain: Public Externally routable: Yes Connected to: controllers
External Provider (FIP)	Network with a pool of externally routable IP addresses used by neutron routers to NAT to/from the tenant RFC1918 private networks	Security Domain: Data Centre Externally routable: Yes Connected to: controllers, OVS computes
External Provider (VLAN)	External Data Centre L2 networks (VLANs) that are directly accessible to the project. Note: External IP address management is required	Security Domain: Data Centre Externally routable: Yes Connected to: OVS DPDK computes
IPMI / Out of Band	The remote “lights-out” management port of the servers e.g., iLO, IDRAC / IPMI / Redfish	Security Domain: Management Externally routable: No Connected to: IPMI port on all servers

Table 65 Logical networks description

A VNF application network topology is expressed in terms of VMs, vNIC interfaces with vNet access networks, and WAN Networks while the VNF Application VMs require multiple vNICs, VLANs, and host routes configured within the VM's Kernel.

4.2.3.3 Octavia v2 API conformant Load Balancing

Load balancing is needed for automatic scaling, managing availability and changes. Octavia **Error! Reference source not found.** is an open-source load balancer for OpenStack, based on HAProxy, and replaces the deprecated (as of OpenStack Queens release) Neutron LbaaS. The Octavia v2 API is a superset of the deprecated Neutron LbaaS v2 API and has a similar CLI for seamless transition.

As a default, Octavia utilises Amphorae Load Balancer. Amphorae consists of a fleet of VMs, containers or bare metal servers and delivers horizontal scaling by managing and spinning these resources on demand. The reference implementation of the Amphorae image is an Ubuntu virtual machine running HAProxy.

Octavia depends upon a number of OpenStack services including Nova for spinning up compute resources on demand and their life cycle management; Neutron for connectivity between the compute resources, project environment and external networks; Keystone for authentication; and Glance for storing of the compute resource images.

Octavia supports provider drivers which allows third-party load balancing drivers (such as F5, AVI, etc.) to be utilised instead of the default Amphorae load balancer. When creating a third-party load balancer, the provider attribute is used to specify the backend to be used to create the load balancer. The list providers list all enabled provider drivers. Instead of using the provider parameter, an alternate is to specify the flavor_id in the create call where provider-specific Octavia flavours have been created.

4.2.3.4 Neutron Extensions

OpenStack Neutron is an extensible framework that allows incorporation through plugins and API Extensions. API Extensions provide a method for introducing new functionality and vendor specific capabilities. Neutron plugins support new or vendor-specific functionality. Extensions also allow specifying new resources or extensions to existing resources and the actions on these resources. Plugins implement these resources and actions.

This Reference Architecture supports the ML2 plugin (see below) as well as the service plugins including for FwaaS (Firewall as a Service) **Error! Reference source not found.**, LbaaS (Load Balancer as a Service) **Error! Reference source not found.**, and VPNaaS (VPN as a Service) **Error! Reference source not found.**. The OpenStack wiki provides a list of Neutron plugins **Error! Reference source not found.**

Every Neutron plugin needs to implement a minimum set of common methods (actions for Train release) **Error! Reference source not found.**. Resources can inherit Standard Attributes and thereby have the extensions for these standard attributes automatically incorporated. Additions to resources, such as additional attributes, must be accompanied by an extension.

Section 5 "Interfaces and APIs" of this Reference Architecture provides a list of "Neutron Extensions". The current available extensions can be obtained using the "List Extensions API" **Error! Reference source not found.** and details about an extension using the "Show extension details API" **Error! Reference source not found.**

Neutron ML2 integration The OpenStack Modular Layer 2 (ML2) plugin simplifies adding networking technologies by utilising drivers that implement these network types and methods

for accessing them. Each network type is managed by an ML2 type driver and the mechanism driver exposes interfaces to support the actions that can be performed on the network type resources. The OpenStack ML2 documentation **Error! Reference source not found.** lists example mechanism drivers.

4.2.3.5 Network quality of service

For VNF workloads, the resource bottlenecks are not only the CPU and the memory but also the I/O bandwidth and the forwarding capacity of virtual and non-virtual switches and routers within the infrastructure. Several techniques (all complementary) can be used to improve QoS and try to avoid any issue due to a network bottleneck (mentioned per order of importance):

1. Nodes interfaces segmentation: Have separated NIC ports for Storage and Tenant networks. Actually, the storage traffic is bursty, especially in case of service restoration after some failure or new service implementation, upgrades, etc. Control and management networks should rely on a separate interface from the interface used to handle tenant networks.
2. Capacity planning: FW, physical links, switches, routers, NIC interfaces and DCGW dimensioning (+ load monitoring: each link within a LAG or a bond shouldn't be loaded over 50% of its maximum capacity to guaranty service continuity in case of individual failure).
3. Hardware choice: e.g., ToR/fabric switches, DCGW and NIC cards should have appropriate buffering and queuing capacity.
4. High Performance compute node tuning (including OVS-DPDK).

4.2.3.6 Integration Interfaces

1. DHCP: When the Neutron-DHCP agent is hosted in controller nodes, then for VMs, on a Tenant network, that need to acquire an IPv4 and/or IPv6 address, the VLAN for the Tenant must be extended to the control plane servers so that the Neutron agent can receive the DHCP requests from the VM and send the response to the VM with the IPv4 and/or IPv6 addresses and the lease time. Please see OpenStack provider Network.
2. DNS
3. LDAP
4. IPAM

4.2.4 Storage Backend

Storage systems are available from multiple vendors and can also utilise commodity hardware from any number of open-source based storage packages (such as LVM, Ceph, NFS, etc.). The proprietary and open-source storage systems are supported in Cinder through specific plugin drivers. The OpenStack Cinder documentation **Error! Reference source not found.** specifies the minimum functionality that all storage drivers must support. The functions include:

1. Volume: create, delete, attach, detach, extend, clone (volume from volume), migrate
2. Snapshot: create, delete, and create volume from snapshot
3. Image: create from volume

The document also includes a matrix for a number of proprietary drivers and some of the optional functions that these drivers support. This matrix is a handy tool to select storage backends that have the optional storage functions needed by the cloud operator. The cloud workload storage requirements help determine the backends that should be deployed by the cloud operator. The common storage backend attachment methods include iSCSI, NFS, local disk, etc. and the matrix lists the supported methods for each of the vendor drivers. The OpenStack Cinder Available Drivers **Error! Reference source not found.** documentation provides a list of all OpenStack compatible drivers and their configuration options.

The Cinder Configuration **Error! Reference source not found.** document provides information on how to configure Cinder including required capabilities for volume encryption, Policy configuration, quotas, etc. The Cinder Administration **Error! Reference source not found.** document provides information on the capabilities required by including managing volumes, snapshots, multi-storage backends, migrate volumes, etc.

Ceph **Error! Reference source not found.** is the default Reference Architecture storage backend and is discussed below.

4.2.4.1 Ceph Storage Cluster

The Ceph storage cluster is deployed on bare metal hardware. The minimal configuration is a cluster of three bare metal servers to ensure High availability. The Ceph Storage cluster consists of the following components:

1. CEPH-MON (Ceph Monitor)
2. OSD (object storage daemon)
3. RadosGW (Rados Gateway)
4. Journal
5. Manager

Ceph monitors maintain a master copy of the maps of the cluster state required by Ceph daemons to coordinate with each other. Ceph OSD handles the data storage (read/write data on the physical disks), data replication, recovery, rebalancing, and provides some monitoring information to Ceph Monitors. The RadosGW provides Object Storage RESTful gateway with a Swift-compatible API for Object Storage.

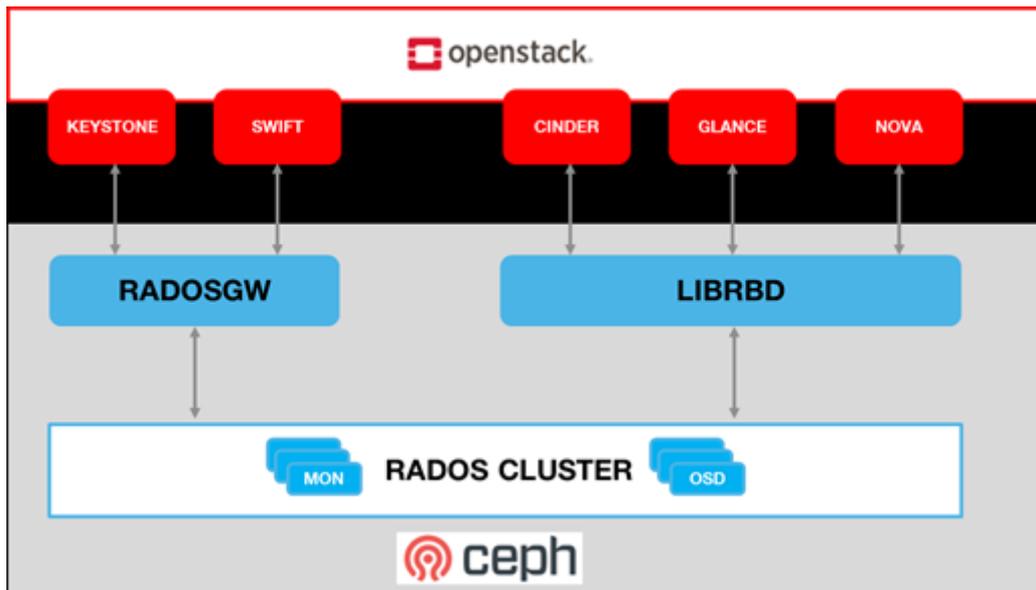

Figure 9 Ceph Storage System.

4.2.4.2 BIOS Requirement for Ceph servers

BIOS/boot Parameter	Value
Boot disks	RAID 1

Table 66 Boot parameter – Ceph server

How many nodes to meet SLA:

1. minimum: three bare metal servers where Monitors are collocated with OSD. Note: at least 3 Monitors and 3 OSDs are required for High Availability.

HW specifications:

2. Boot disks are dedicated with Flash technology disks
3. For an IOPS oriented cluster (Flash technology), the journal can be hosted on OSD disks
4. For a capacity-oriented cluster (HDD), the journal must be hosted on dedicated Flash technology disks

Sizing rules:

5. Minimum of 6 disks per server
6. Replication factor: 3
7. 1 Core-GHz per OSD
8. 16GB RAM baseline + 2-3 GB per OSD

4.3 Virtualised Infrastructure Manager (VIM)

This section covers:

1. Detailed breakdown of OpenStack core services
2. Specific build-time parameters

4.3.1 VIM Services

A high-level overview of the core OpenStack Services was provided in section 3. In this section we describe the core and other needed services in more detail.

4.3.1.1 Keystone

Keystone is the authentication service, the foundation of identity management in OpenStack. Keystone needs to be the first deployed service. Keystone has services running on the control nodes and no services running on the compute nodes:

1. Keystone admin API
2. Keystone public API – in Keystone V3 this is the same as the admin API

4.3.1.2 Glance

Glance is the image management service. Glance has only a dependency on the Keystone service therefore it is the second one deployed. Glance has services running on the control nodes and no services running on the compute nodes:

1. Glance API
2. Glance Registry

The Glance backends include Swift, Ceph RBD and NFS.

4.3.1.3 Cinder

Cinder is the block device management service, depends on Keystone and possibly Glance to be able to create volumes from images. Cinder has services running on the control nodes and no services running on the compute nodes:

1. Cinder API
2. Cinder Scheduler
3. Cinder Volume – the Cinder volume process needs to talk to its backends

The Cinder backends include SAN/NAS storage, iSCSI drives, Ceph RBD and NFS.

4.3.1.4 Swift

Swift is the object storage management service, depends on Keystone and possibly Glance to be able to create volumes from images. Swift has services running on the control nodes and the compute nodes:

1. Proxy Services
2. Object Services
3. Container Services
4. Account Services

The Swift backends include iSCSI drives, Ceph RBD and NFS.

4.3.1.5 Neutron

Neutron is the networking service, depends on Keystone and has services running on the control nodes and the compute nodes. Depending upon the workloads to be hosted by the Infrastructure, and the expected load on the controller node, some of the Neutron services can run on separate network node(s). Factors affecting controller node load include number of compute nodes and the number of API calls being served for the various OpenStack services (nova, neutron, cinder, glance etc.). To reduce controller node load, network nodes are widely added to manage L3 traffic for overlay tenant networks and interconnection with external networks. **Error! Reference source not found.** below lists the networking service components and their placement. Please note that while network nodes are listed in the table below, network nodes only deal with tenant networks and not provider networks. Also, network nodes are not required when SDN is utilised for networking.

Networking Service component	Description	Required or Optional Service	Placement
neutron server (neutron-server and neutron-*-plugin)	Manages user requests and exposes the Neutron APIs	Required	Controller node
DHCP agent (neutron-dhcp-agent)	Provides DHCP services to tenant networks and is responsible for maintaining DHCP	Optional depending upon plug-in	Network node (Controller node if no network node present)

Networking Service component	Description	Required or Optional Service	Placement
	configuration. For High availability, multiple DHCP agents can be assigned.		
L3 agent (neutron-l3-agent)	Provides L3/NAT forwarding for external network access of VMs on tenant networks and supports services such as Firewall-as-a-service (FwaaS) Error! Reference source not found. and Load Balancer-as-a-service (LbaaS) Error! Reference source not found.	Optional depending upon plug-in	Network node (Controller node if no network node present) NB in DVR based OpenStack Networking, also in all Compute nodes.
Neutron metadata agent (neutron-metadata-agent)	The metadata service provides a way for instances to retrieve instance-specific data. The networking service, neutron, is responsible for intercepting these requests and adding HTTP headers which uniquely identify the source of the request before forwarding it to the metadata API server. These functions are performed by the neutron metadata agent.	Optional	Network node (Controller node if no network node present)
neutron plugin agent (neutron-*-agent)	Runs on each compute node to control and manage the local virtual network driver (such as the Open vSwitch Error! Reference source not found. or Linux Bridge) configuration and local networking configuration for VMs hosted on that node.	Required	Every Compute Node

Table 67 Neutron Services Placement

Issues with the standard networking (centralized routing) approach

The network node performs both routing and NAT functions and represents both a scaling bottleneck and a single point of failure.

4.3.1.5.1 Consider two VMs on different compute nodes and using different project networks (a.k.a. tenant networks) where both of the project networks are connected by a project router. For communication between the two VMs (instances with a fixed or floating IP address), the network node routes East-West network traffic among project networks using the same project router. Even though the instances are connected by a router, all routed traffic must flow through the network node, and this becomes a bottleneck for the whole network.

While the separation of the routing function from the controller node to the network node provides a degree of scaling it is not a truly scalable solution. We can either add additional cores/compute-power or network node to the network node cluster, but, eventually, it runs out of processing power especially with high throughput requirement. Therefore, for scaled deployments, there are multiple options including use of Dynamic Virtual Routing (DVR) and Software Defined Networking (SDN).

Distributed Virtual Routing (DVR)

4.3.1.5.2 With DVR, each compute node also hosts the L3-agent (providing the distributed router capability) and this then allows direct instance to instance (East-West) communications.

The OpenStack “High Availability Using Distributed Virtual Routing (DVR)” **Error! Reference source not found.** provides an in-depth view into how DVR works and the traffic flow between the various nodes and interfaces for three different use cases. Please note that DVR was introduced in the OpenStack Juno release and, thus, its detailed analysis in the Liberty release documentation is not out of character for OpenStack documentation.

DVR addresses both scalability and high availability for some L3 functions but is not fully fault tolerant. For example, North/South SNAT traffic is vulnerable to single node (network node) failures. DVR with VRRP **Error! Reference source not found.** addresses this vulnerability.

4.3.1.5.3

Software Defined Networking (SDN)

For the most reliable solution that addresses all the above issues and Telco workload requirements requires SDN to offload Neutron calls.

SDN provides a truly scalable and preferred solution to support dynamic, very large-scale, high-density, telco cloud environments. OpenStack Neutron, with its plugin architecture, provides the ability to integrate SDN controllers (3.2.5. Virtual Networking – 3rd party SDN solution). With SDN incorporated in OpenStack, changes to the network are triggered by workloads (and users), translated into Neutron APIs and then handled through neutron plugins by the corresponding SDN agents.

4.3.1.6 Nova

Nova is the compute management service, depends on all above components and is deployed after their deployment. Nova has services running on the control nodes and the compute nodes:

1. nova-metadata-api
2. nova-compute api
3. nova-consoleauth
4. nova-scheduler
5. nova-conductor
6. nova-novncproxy
7. nova-compute-agent which runs on Compute node

Please note that the Placement-API must have been installed and configured prior to nova compute starts.

4.3.1.7 Ironic

Ironic is the bare metal provisioning service. Ironic depends on all above components and is deployed after them. Ironic has services running on the control nodes and the compute nodes:

1. Ironic API
2. ironic-conductor which executes operation on bare metal nodes

Note: This is an optional service. As Ironic is currently not invoked directly (only invoked through other services such as Nova) hence its APIs will not be specified.

4.3.1.8 Heat

Heat is the orchestration service using templates to provision cloud resources, Heat integrates with all OpenStack services. Heat has services running on the control nodes and no services running on the compute nodes:

1. heat-api
2. heat-cfn-api
3. heat-engine

4.3.1.9 Horizon

Horizon is the Web User Interface to all OpenStack services. Horizon has services running on the control nodes and no services running on the compute nodes.

4.3.1.10 Placement

The OpenStack Placement service **Error! Reference source not found.** enables tracking (or accounting) and scheduling of resources. It provides a RESTful API and a data model for the managing of resource provider inventories and usage for different classes of resources. In addition to standard resource classes, such as vCPU, MEMORY_MB and DISK_GB, the Placement service supports custom resource classes (prefixed with "CUSTOM_") provided by some external resource pools such as a shared storage pool provided by, say, Ceph. The placement service is primarily utilised by nova-compute and nova-scheduler. Other OpenStack services such as Neutron or Cyborg can also utilise placement and do so by

creating Provider Trees **Error! Reference source not found.**. The following data objects are utilised in the placement service **Error! Reference source not found.**:

1. Resource Providers provide consumable inventory of one or more classes of resources (CPU, memory or disk). A resource provider can be a compute host, for example.
2. Resource Classes specify the type of resources (vCPU, MEMORY_MB and DISK_GB or CUSTOM_*)
3. Inventory: Each resource provider maintains the total and reserved quantity of one or more classes of resources. For example, RP_1 has available inventory of 16 vCPU, 16384 MEMORY_MB and 1024 DISK_GB.
4. Traits are qualitative characteristics of the resources from a resource provider. For example, the trait for RPA_1 “is_SSD” to indicate that the DISK_GB provided by RP_1 are solid state drives.
5. Allocations represent resources that have been assigned/used by some consumer of that resource.
6. Allocation candidates is the collection of resource providers that can satisfy an allocation request.

The Placement API is stateless and, thus, resiliency, availability, and scaling, it is possible to deploy as many servers as needed. On start, the nova-compute service will attempt to make a connection to the Placement API and keep attempting to connect to the Placement API, logging and warning periodically until successful. Thus, the Placement API must be installed and enabled prior to Nova compute.

Placement has services running on the control node:

1. nova-placement-api

4.3.1.11 Barbican

Barbican **Error! Reference source not found.** is the OpenStack Key Manager service. It is an optional service hosted on controller nodes. It provides secure storage, provisioning, and management of secrets as passwords, encryption keys and X.509 Certificates. Barbican API is used to centrally manage secrets used by OpenStack services, e.g., symmetric encryption keys used for Block storage encryption or Object Storage encryption or asymmetric keys and certificates used for Glance image signing and verification.

Barbican usage provides a means to fulfil security requirements such as sec.sys.012 “The Platform must protect all secrets by using strong encryption techniques and storing the protected secrets externally from the component” and sec.ci.001 “The Platform must support Confidentiality and Integrity of data at rest and in transit”.

4.3.2 Containerised OpenStack Services

Containers are lightweight compared to Virtual Machines and leads to efficient resource utilization. Kubernetes auto manages scaling, recovery from failures, etc. Thus, it is recommended that the OpenStack services be containerised for resiliency and resource efficiency.

In section 3, [Error! Reference source not found.](#) shows a high level Virtualised OpenStack services topology. The containerised OpenStack services topology version is shown in [Error! Reference source not found.](#).

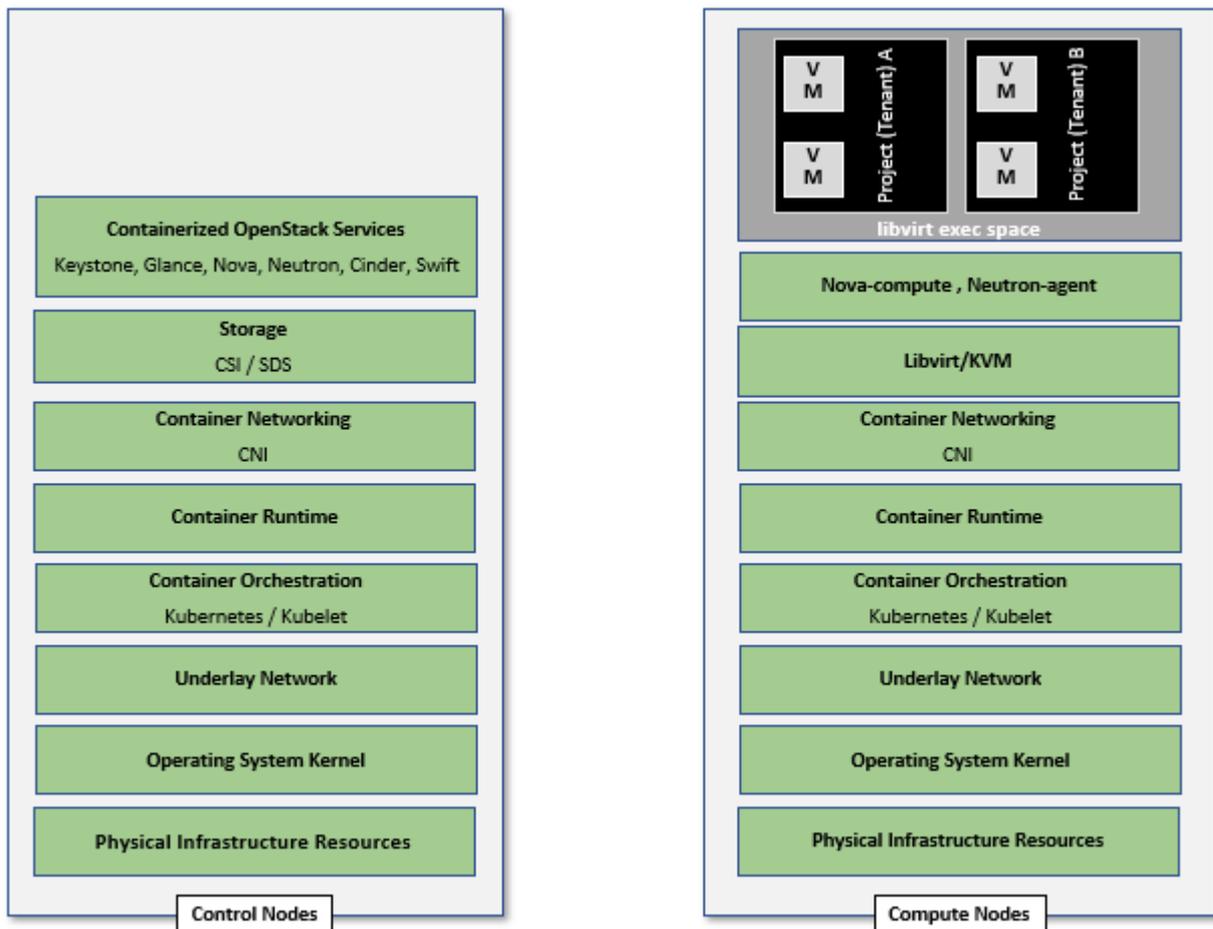

Figure 10 Containerized OpenStack Services Topology.

4.4 Consumable Infrastructure Resources and Services

4.4.1 Support for Cloud Infrastructure Profiles and flavours

Reference Model 0 sections 4 and 5 provide information about the Cloud Infrastructure Profiles and their size information. OpenStack flavours with their set of properties describe the VM capabilities and size required to determine the compute host which will run this VM. The set of properties must match compute profiles available in the infrastructure. To implement these profiles and sizes, it is required to set up the flavours as specified in the tables below.

Flavor Capabilities	Reference RM section 4 and 5	Basic	High Performance
CPU allocation ratio (custom extra_specs)	infra.com.cfg.001	In flavor create or flavor set --property cpu_allocation_ratio=4.0	In flavor create or flavor set --property cpu_allocation_ratio=1.0
NUMA Awareness	infra.com.cfg.002		In flavor create or flavor set specify --property hw:numa_nodes=<integer range of 0 to #numa_nodes - 1> To restrict an instance's vCPUs to a single host NUMA node, specify: --property hw:numa_nodes=1 Some compute intensive* workloads with highly sensitive memory latency or bandwidth requirements, the instance may benefit from spreading across multiple NUMA nodes: --property hw:numa_nodes=2
CPU Pinning	infra.com.cfg.003	In flavor create or flavor set specify --property hw:cpu_policy=shared (default)	In flavor create or flavor set specify --property hw:cpu_policy=dedicated and --property hw:cpu_thread_policy=<prefer, require, isolate> Use "isolate" thread policy for very high compute intensive workloads that require that each vCPU be placed on a different physical core
Huge Pages	infra.com.cfg.004		--property hw:mem_page_size=<small large size>
SMT	infra.com.cfg.005		In flavor create or flavor set specify --property

Flavor Capabilities	Reference RM section 4 and 5	Basic	High Performance
			hw.cpu_threads=<integer #threads (usually 1 or 2)>
OVS-DPDK	infra.net.acc.cfg.001		ml2.conf.ini configured to support [OVS] datapath_type=netdev Note: huge pages should be configured to large
Local Storage SSD	infra.hw.stg.ssd.cfg.002	trait:STORAGE_DISK_SSD=required	trait:STORAGE_DISK_SSD=required
Port speed	infra.hw.nic.cfg.002	--property quota vif_inbound_average=1310720 and vif_outbound_average=1310720 Note: 10 Gbps = 1250000 kilobytes per second	--property quota vif_inbound_average=3125000 and vif_outbound_average=3125000 Note: 25 Gbps = 3125000 kilobytes per second

Table 68 Flavours properties per profile

To configure profile-extensions, for example, the “Storage Intensive High Performance” profile, as defined in Reference Model Profile Extensions (RM 0 section 2.4.2),

in addition to the above, need to configure the storage IOPS: the following two parameters need to be specified in the flavour create: --property quota:disk_write_iops_sec=<IOPS#> and --property quota:disk_read_iops_sec=<IOPS#>.

The flavour create command and the mandatory and optional configuration parameters are documented in **Error! Reference source not found.**

4.4.2 Logical segregation and high availability

To ensure logical segregation and high availability, the architecture relies on the following principles:

1. Availability zone: provide resiliency and fault tolerance for VNF deployments, by means of physical hosting distribution of compute nodes in separate racks with separate power supply, in the same or different DC room
2. Affinity-groups: allow tenants to make sure that VNFC instances are on the same compute node or are on different compute nodes.

Note: The Cloud Infrastructure doesn't provide any resiliency mechanisms at the service level. Any VM restart shall be triggered by the VNF Manager instead of OpenStack:

3. It doesn't implement Instance High Availability which could allow OpenStack Platform to automatically re-spawn instances on a different compute node when their host compute node breaks.
4. Physical host reboot does not trigger automatic VM recovery.
5. Physical host reboot does not trigger the automatic start of VM.

Limitations and constraints

1. NUMA Overhead: isolated core will be used for overhead tasks from the hypervisor.

4.4.3 Transaction Volume Considerations

Storage transaction volumes impose a requirement on North-South network traffic in and out of the storage backend. Data availability requires that the data be replicated on multiple storage nodes and each new write imposes East-West network traffic requirements.

4.5 Cloud Topology and Control Plane Scenarios

Typically, Clouds have been implemented in large (central) data centres with hundreds to tens of thousands of servers. Telco Operators have also been creating intermediate data centres in central office locations, colocation centres, and now edge centres at the physical edge of their networks because of the demand for low latency and high throughput for 5G, IoT and connected devices (including autonomous driverless vehicles and connected vehicles). Section 3.5 of this document, discusses "Cloud Topology" and lists 3 types of data centres: Large, Intermediate and Edge.

For ease of convenience, unless specifically required, in this section we will use Central Cloud Centre, Edge Cloud Centre and Intermediate Cloud Centre as representative terms for cloud services hosted at centralised large data centres, Telco edge locations and for locations with capacity somewhere in between the large data centres and edge locations, respectively. The mapping of various terms, including the Reference Model 0 terminology specified in Section 8.3.5 and the "Open Glossary of Edge Computing" **Error! Reference source not found.** is as follows:

1. Central Cloud Centre: Large Centralised Data Centre, Regional Data Centre
2. Intermediate Cloud Centre: Metro Data Centre, Regional Edge, Aggregation Edge
3. Edge Cloud Centre: Edge, Mini-/Micro-Edge, Micro Modular Data Centre, Service Provider Edge, Access Edge, Aggregation Edge

In the Intermediate and Edge cloud centres, there may be limitations on the resource capacity, as in the number of servers, and the capacity of these servers in terms of # of cores, RAM, etc. restricting the set of services that can be deployed and, thus, creating a dependency between other data centres. In Reference Model 0, section 8.3 "Telco Edge Cloud" specifies the physical and environmental characteristics, infrastructure capabilities and deployment scenarios of different locations.

Section 3.3.1.1 “OpenStack Services Topology” of this document, specifies the differences between the Control Plane and Data Plane, and specifies which of the control nodes, compute nodes, storage nodes (optional) and network nodes (optional) are components of these planes. The previous subsections of this Section 4 include a description of the OpenStack services and their deployment in control nodes, compute nodes, and optionally storage nodes and network nodes (rarely). The Control Plane deployment scenarios determine the distribution of OpenStack and other needed services among the different node types. This section considers the Centralised Control Plane (CCP) and Distributed Control Plane (DCP) scenarios. The choice of control plane and the cloud centre resource capacity and capabilities determine the deployment of OpenStack services in the different node types.

The Central Cloud Centres are organized around a Centralised Control Plane. With the introduction of Intermediate and Edge Cloud Centres, the Distributed Control Plane deployment becomes a possibility. A number of independent control planes (sometimes referred to as Local Control Planes (LCP)) exist in the Distributed Control Plane scenario, compared with a single control plane in the Centralised Control Plane scenario. Thus, in addition to the control plane and controller services deployed at the Central Cloud Centre, Local Control Planes hosting a full-set or subset of the controller services are also deployed on the Intermediate and Edge Cloud Centres. **Error! Reference source not found.** presents examples of such deployment choices.

		Orchestration	Identity Management	Image Management	Compute	Network Management	Storage Management
CCP	Centralized DC – control nodes	heat-api, heat-engine, nova-placement-api	Identity Provider (IdP), Keystone API	Glance API, Glance Registry	nova-compute api, nova-scheduler, nova-conductor	neutron-server, neutron-dhcp-agent, neutron-L2-agent, neutron-L3-agent (optional), neutron-metadata-agent	Cinder API, Cinder Scheduler, Cinder Volume

		Orchestration	Identity Management	Image Management	Compute	Network Management	Storage Management
DCP: combination of services depending upon Centre size	Any DC – Control nodes Option 1	heat-api, heat-engine, nova-placement-api	Identity Provider (IdP), Keystone API	Glance API, Glance Registry	nova-compute-api, nova-scheduler, nova-conductor	neutron-server, neutron-dhcp-agent, neutron-L2-agent, neutron-L3-agent (optional), neutron-metadata-agent	Cinder API, Cinder Scheduler, Cinder Volume
	Any DC – Control nodes Option 2: split services between DCs	** in other DC	* in Large DC	* in Large DC	** in another DC	** in another DC	** in another DC
CCP or DCP	Compute nodes				nova-compute-agent	neutron-L2-agent, neutron-L3-agent (optional)	
CCP	Compute nodes	nova-placement-api			nova-compute-agent, nova-conductor	neutron-server, neutron-dhcp-agent, neutron-L2-agent, neutron-L3-agent (optional)	

Table 69 Distribution of OpenStack services on different nodes depending upon Control Plane Scenario

4.5.1 Edge Cloud Topology

The Reference Model 0 section 8.3 “Telco Edge Cloud” presents the deployment environment characteristics, infrastructure characteristics and new values for the Infrastructure Profiles at the Edge.

The Edge computing whitepaper **Error! Reference source not found.** includes information such as the services that run on various nodes. The information from the whitepaper coupled with that from the OpenStack Reference Deployment Architecture for 100, 300 and 500 nodes will help in deciding which OpenStack and other services (such as database, messaging) run on which nodes in what Cloud Centre and the number of copies that should be deployed. These references also present the pros and cons of DCP and CCP and designs to address some of the challenges of each of the models.

The Reference Model 0 section 8.3.4 “Telco Edge Cloud: Platform Services Deployment” lists the Platform Services that may be placed in the different node types (control, compute and storage). Depending upon the capacity and resources available only the compute nodes may exist at the Edge thereby impacting operations.

The Reference Model 0 section 8.3.3 “Telco Edge Cloud Infrastructure Profiles” lists a number of Infrastructure Profile characteristics and the changes that may need to be made for certain Edge clouds depending upon their resource capabilities. It should be noted that none of these changes affect the definition of OpenStack flavours.

4.5.1.1 Edge Cloud Deployment

Deployment at the Edge requires support for large scale deployment. A number of open-source tools are available for this purpose including:

1. Airship **Error! Reference source not found.**: declaratively configure, deploy and maintain an integrated virtualization and containerization platform
2. Starling-X **Error! Reference source not found.**: cloud infrastructure software stack for the edge
3. Triple-O **Error! Reference source not found.**: for installing, upgrading, and operating OpenStack clouds

The Reference Implementation (RI-1) is responsible to choose the tools for the implementation and shall specify implementation and usage details of the chosen tools.

5 Interfaces and APIs

5.1 Introduction

This section presents a consolidated set of OpenStack Service APIs corresponding to the ETSI NFV Nf-Vi, Vi-Vnfm and Or-Vi interfaces. The OpenStack Train version is used as the baseline for these APIs and CLIs in this Reference Architecture (RA-1) version. Any Cloud Infrastructure + VIM reference implementations that get certified by RC can be considered as RA Conformant.

This section presents the APIs for the core OpenStack services defined in section 3 and a consolidated view of these and other APIs that are of interest.

OpenStack is a multi-project framework composed of independently evolving services. It is not enough to rely only on the OpenStack release to characterise the capabilities supported by these services. Regarding OpenStack services APIs, an “API version” is associated with each OpenStack service. In addition to major API versions, some OpenStack services (Nova, Glance, Keystone, Cinder...) support microversions. The microversions allow new

features to be introduced over time. In this section, the major version and microversion are specified per service. The specified microversion is the microversion that supports all the features requested for this RA. For the purpose of conformance tests, this section also identifies the set of features, offered by a service, that are mandatory for compliant implementation.

5.2 Core OpenStack Services APIs

OpenStack provides a maximum microversion to be used with an OpenStack release. Please note that in Reference Conformance (RC-1) testing, the System Under Test (SUT) can utilise newer microversions because of the OpenStack microversion policies. As per multiple OpenStack services documentation, for example the Compute Service **Error! Reference source not found.**, “A cloud that is upgraded to support newer microversions will still support all older microversions to maintain the backward compatibility for those users who depend on older microversions.” Therefore, in the following sections the “Minimal API Microversion” refers to this maximum microversion specified for the OpenStack Train release.

5.3 Consolidated Set of APIs

5.3.1 OpenStack Interfaces

This section illustrates some of the Interfaces provided by OpenStack; the exhaustive list of APIs is available at [Error! Reference source not found.](#)

OpenStack REST APIs are simple to interact with using either of two options. Clients can either call the APIs directly using the HTTP or REST library, or they can use one of the many cloud specific programming language libraries.

APIs

OpenStack Service	Link for API list	API Version	Minimal API Microversion

6 Security

6.1 Introduction

This guide is intended to provide basic security requirements to architects who are implementing Cloud Infrastructure using OpenStack technology. This is a minimal set of high-level general security practices, not intended to cover all implementation scenarios. Please ensure to also reference your enterprise security and compliance requirements in addition to this guide.

6.2 Security Requirements

Section 2 gathers all requirements and recommendations regarding security topics developed in this section.

6.3 Cloud Infrastructure and VIM Security

In the “Security boundaries and threats” section of the OpenStack security guide **Error! Reference source not found.**, there is extensive description on security domains, threat classifications, and attack vectors. The following only touches on some of the topics and at a high level.

6.3.1 System Hardening

All infrastructure components should undergo system hardening, establish processes to govern the hardening, and documents to cover at a minimal for the following areas.

6.3.1.1 Server boot hardening

Server boot process must be trusted. For this purpose, the integrity and authenticity of all BIOS firmware components must be verified at boot. Per sec.gen.003 requirements, Secure Boot based on UEFI must be used. By verifying the signatures of all BIOS components, Secure Boot will ensure that servers start with the firmware expected and without malware insertion into the system.

Secure Boot checks the digital signatures locally. To implement a chain of trust, Secure Boot must be complemented by the use of a hardware-based Root of Trust provided by a TPM (Trusted Platform Module).

6.3.1.2 System Access

Access to all the platform's components must be restricted (sec.gen.013) applying the following rules:

1. Remove, or at a minimal, disable all unnecessary user accounts
2. Change all default user accounts where technically feasible
3. Change all default credentials
4. Prohibit logging with root account when root privileges are not required (sec.gen.006)
5. Restrict access according to only those protocols/service/address adhering to the Principle of Least Privilege
6. The same authentication credentials must not be reused on different components (sec.sys.011)
7. Restrict access to Operating System (sec.gen.005)

6.3.1.3 Password policy

For all infrastructure components, passwords must be hardened, and a strict password policy must be applied (sec.gen.002).

Passwords must be strengthened:

1. All vendors default passwords must be changed
2. Passwords must contain at least 8 characters as a minimal value, 14 characters' length passwords are recommended
3. Passwords must contain at least one upper case letter, one lower case letter and one non-alphabetic character
4. For administration privileges accounts, passwords must contain at least one upper case letter, one lower case letter, one numeral and one special (non-alphanumeric) character

For password updates, the user must be authenticated prior to permitting a password change.

Passwords must be encrypted at rest and in-transit. Password files must be stored separately from application system data.

Password's composition, complexity and policy should follow the recommendations consolidated within the CIS Password Policy guide **Error! Reference source not found.** such as:

1. Check the password for known bad passwords (repetitive or sequential characters, dictionary words, context-specific words, previously used passwords, etc.)
2. Limit number of failed login attempts
3. Implement Multi-Factor Authentication
4. Periodic (for example, Yearly, Quarterly, etc.) password change or on key events such as indication of compromise, change of user roles, a defined period of inactivity, when a user leaves the organisation, etc.

6.3.1.4 Function and Software

Infrastructure must be implemented to perform at least the minimal functions needed to operate the Cloud Infrastructure.

Regarding software (sec.gen.004):

1. Install only software which is required to support the functions
2. Remove any unnecessary software or packages
3. Where software cannot be removed, disable all services to it

6.3.1.5 Patches

All deployed Cloud Infrastructure software must be audited and must be implemented to allow installation of the latest patches to address security vulnerabilities in the following timescale from discovery (sec.gen.008, sec.lcm.011):

Severity	Time to Remediate
Zero-Day	Immediately or as soon as practically possible
Critical	30 days
High	60 days
Medium	90 days
Low	180 days

Table 85 Timescale remediation

See Common Vulnerability Scoring System **Error! Reference source not found.** (and NIST Vulnerability Metrics **Error! Reference source not found.**).

6.3.1.6 Network Protocols

1. Only allow protocols that are required by the system functions(sec.sys.002)
2. Tighten all required TCP/IP (Transmission Control Protocol/Internet Protocol) services

6.3.1.7 Anti-Virus and Firewall

1. Install and run your Enterprise approved anti-virus software/ intrusion protection/ malware/ spyware endpoint security software with up-to-date profiles; minimal daily refresh
2. Install and run firewall software where applicable

6.3.1.8 Vulnerability Detection and Prevention

1. Implement DoS (Denial of Service) protection where applicable
2. Ensure logging and alerting is actively running
3. Run host-based scanning and fix all findings per vulnerability severity
4. Run network-based scanning and fix all findings per vulnerability severity

6.3.2 Platform Access

6.3.2.1 Identity Security

The OpenStack Identity service (Keystone) **Error! Reference source not found.** provides identity, token, catalog, and policy services for use specifically by services in the OpenStack family. Identity service is organised as a group of internal services exposed on one or many endpoints. Many of these services are used in a combined fashion by the front end (sec.sys.006).

OpenStack Keystone can work with an Identity service that your enterprise may already have, such as LDAP with Active Directory. In those cases, the recommendation is to integrate Keystone with the cloud provider's Identity Services.

6.3.2.2 Authentication

Authentication is the first line of defence for any real-world implementation of OpenStack. At its core, authentication is the process of confirming the user logging in is who they claim to be. OpenStack Keystone supports multiple methods of authentication, such as username/password, LDAP, and others. For more details, please refer to the "Authentication Methods" section in **Error! Reference source not found.**

Limiting the number of repeated failed login attempts (configurable) reduces the risk of unauthorised access via password guessing (Bruce force attack) – sec.mon.006. The restriction on the number of consecutive failed login attempts ("lockout_failure_attempts") and any actions post such access attempts (such as locking the account where the "lockout_duration" is left unspecified) should abide by the operator's policies. For example, an operator may restrict the number of consecutive failed login attempts to 3 ("lockout_failure_attempts = 3") and lock the account preventing any further access and where the account is unlocked by getting necessary approvals.

6.3.2.3 Keystone Tokens

Once a user is authenticated, a token is generated for authorisation and access to an OpenStack environment and resources. By default, the token is set to expire in one hour. This setting can be changed based on the business and operational needs, but it's highly recommended to set the expiration to the shortest possible value without dramatically impacting your operations.

Special Note on Logging Tokens: since the token would allow access to the OpenStack services, it *MUST* be masked before outputting to any logs.

6.3.2.4 Authorisation

Authorisation serves as the next level of defence. At its core, it checks if the authenticated users have the permission to execute an action. Most Identity Services support the notion of groups and roles. A user belongs to groups and each group has a list of roles that permits certain actions on certain resources. OpenStack services reference the roles of the user attempting to access the service. OpenStack policy enforcer middleware takes into consideration the policy rules associated with each resource and the user's group/roles and association to determine if access will be permitted for the requested resource. For more

details on policies, please refer to the OpenStack “Policies” section in **Error! Reference source not found.**

6.3.2.5 RBAC

In order to properly manage user access to OpenStack services, service providers must utilise the Role Based Access Control (RBAC) system (sec.sys.001, sec.sys.007). Based on the OpenStack Identify Service (Keystone v3) Group and Domain component, the RBAC system implements a set of access roles that accommodate most use cases. Operations staff can create users and assign them to roles using standard OpenStack commands for users, groups, and roles.

Keystone provides three default roles **Error! Reference source not found.:** admin, member, and reader. As of the Train release, Keystone applies the following personas consistently across its API.

1. The reader role provides read-only access to resources within the system, a domain, or a project (tenant).
2. The member role is the same as reader in Keystone but allows to introduce granularity between admin and reader to other OpenStack services.
3. The admin role is reserved for the most privileged operations within a given scope for managing resources.

For specific use-case, policies can be overridden, and new roles can be created for each OpenStack service by editing the policy. json file.

Rules

The following rules govern create, read, update, and delete (CRUD) level access.

1. *member* can create, read, update, and delete the resources defined at the tenant level.
2. *support_member* can create and read the resources defined at the tenant level.
3. *viewer* can read the resources defined at the tenant level.
4. *admin* can create, read, update, and delete all resources.

Recommended Default Roles to Start

site_admin (HIGHLY RESTRICTED)

1. *Site Level Super Admin* – usually assign to Operation Staffs who already have root level access to hosts
2. Permission to create/read/update/delete all tenants and resources at the site, including creating snapshot and upload public images
3. Limited ability to create/read/update/delete tenant projects

site_admin_support

1. *Site Level Admin* – usually assign to Operation Staffs who need to manage resource except delete
2. Permission to create/read/update all tenants and resources at the site
3. Cannot create snapshots

site_admin_viewer

1. *Site Level Admin Read Only* – usually assign to groups who need to view all resources, such as Capacity Planners
2. Permission to read all tenants and resources at the site
3. Cannot create/update/delete

site_image_manager

1. Site wide admin level privileges to Glance API (via CLI)
2. Restricted to Image team

tenant_member

1. *Tenant Level Admin* – typically assign to majority of tenant users to manage their resources
2. Permission to create/read/update/delete to all resources at the tenant project level
3. Cannot upload image or create snapshot
4. Cannot touch any other tenant except the one the role is located

tenant_snapshot_member

1. *Tenant Level Admin with Snapshot* – typically assign to tenant users who need to create snapshot via special request to Operations Staff
2. Permission is same as tenant_member except the user can also create snapshots

tenant_support_member

1. *Tenant Level Support* – typically assign to tenant users who need to create resource in the project space
2. Permission to create/read all resources at the tenant project level
3. Cannot update/delete or create snapshots

tenant viewer

1. *Tenant Level Read Only* – typically assign to tenant users who need to read all resources in the project space
2. Permission to read all resources at the tenant level
3. Cannot create/update/delete

6.3.3 Confidentiality and Integrity

Confidentiality implies that data and resources must be protected against unauthorised introspection/exfiltration. Integrity implies that the data must be protected from unauthorised modifications or deletions.

Regarding confidentiality and integrity in Cloud Infrastructure, 2 main concerns are raised:

1. confidentiality and integrity of the Cloud Infrastructure components (networks, hypervisor, OpenStack services)
2. confidentiality and integrity of the tenant's data

The Cloud Infrastructure must also provide the mechanism to identify corrupted data.

6.3.3.1 Confidentiality and Integrity of communications (sec.ci.001)

It is essential to secure the infrastructure from external attacks. To counter this threat, API endpoints exposed to external networks must be protected by either a rate-limiting proxy or web application firewall (WAF), and must be placed behind a reverse HTTPS proxy (sec.mon.008). Attacks can also be generated by corrupted internal components, and for this reason, it is security best practice to ensure integrity and confidentiality of all network communications (internal and external) by using Transport Layer Security (TLS) protocol (sec.sys.003, sec.sys.004). When using TLS, according to the OpenStack security guide **Error! Reference source not found.** recommendation, the minimum version to be used is TLS 1.2.

3 categories of traffic will be protected using TLS:

- a) traffic from and to external domains
- b) communications between OpenStack components (OpenStack services, Bus message, Data Base)
- c) management traffic

Certificates used for TLS encryption must be compliant with X.509 standards and be signed by a trusted authority (sec.sys.017). To issue certificates for internal OpenStack users or services, the cloud provider can use a Public Key Infrastructure (PKI) with its own internal Certification Authority (CA), certificate policies, and management.

6.3.3.2 Integrity of OpenStack components configuration

The cloud deployment components/tools store all the information required to install the infrastructure including sensitive information such as credentials. It is recommended to turn off deployment components after deployment to minimise the attack surface area, limit the risk of compromise, and to deploy and provision the infrastructure through a dedicated network (VLAN).

Configuration files contain sensitive information. These files must be protected from malicious or accidental modifications or deletions by configuring strict access permissions for such files. All access, failed attempts to change and all changes (pre-change, post-change and by who) must be securely logged, and all failed access and failed changes must be alerted on (sec.mon.005).

The Cloud Infrastructure must provide the mechanisms to identify corrupted data (sec.gen.009):

1. the integrity of configuration files and binaries must be checked by using cryptographic hash
2. it is recommended to run scripts (such as checksec.sh) to verify the properties of the QEMU/KVM
3. it is recommended to use tools such as CIS-CAT (Center for Internet security- Configuration Assessment Tool **Error! Reference source not found.**) to check the compliance of systems configuration against respective CIS benchmarks **Error! Reference source not found.**

It is strongly recommended to protect all repositories, such as Linux repositories and Docker registries, against the corruption of their data and unauthorised access, by adopting

protection measures such as hosting a local repository/registry with restricted and controlled access, and using TLS (sec.img.004, sec.img.005, sec.img.006). This repository/registry must contain only signed images or packages.

6.3.3.3 Confidentiality and Integrity of tenant data (sec.ci.001)

Tenant data are forwarded unencrypted over the network. Since the VNF is responsible for its security, it is up to the VMs to establish a secure data plane, e.g., using IPsec over its tenant network.

A Cloud actor must not be able to retrieve secrets used by VNF managers. All communications between the VNFM or orchestrator, and the infrastructure must be protected in integrity and confidentiality (e.g., by using TLS) and controlled via appropriate IP filtering rules (sec.lcm.006).

The Cloud Infrastructure must on board only trusted and verified VM images, implying that VNF vendors provide signed images (sec.img.001); images from non-trusted sources may contain security breaches or unsolicited malicious code (spoofing, information disclosure). It is recommended to scan all VM images with a vulnerability scanner (sec.img.002). The scan is mandatory for images from unknown or untrusted sources.

To mitigate tampering attacks, it is recommended to use the Glance image signing feature **Error! Reference source not found.** to validate an image when uploading. In this case, Barbican service must be installed.

In order to protect data, VNFs must encrypt the volumes they use. In this case, the encryption key must not be stored on the infrastructure. When a key management service is provided by the infrastructure, OpenStack can encrypt data on behalf of tenants (sec.gen.010). It is recommended to rely on Barbican, as the key manager service of OpenStack.

6.3.4 Workload Security

OpenStack segregates its infrastructure (sec.ci.008) (for example, hosts) by Regions, Host Aggregates and Availability Zones (AZ). Workloads can also be segregated by server groups (affinity and non-affinity groups) (sec.sys.008). These options support the workloads placement requirement (sec.wl.001, sec.wl.004).

Separation of non-production and production workloads, or by workload category (for example, payment card information, healthcare, etc.) requires separation through server groups (for example, Regions, AZs) but also requires network and storage segregation as in Regions, but also AZs if engineered to do so. Thus, the separation of these workloads is handled through placement of workloads in separate AZs and/or Regions (sec.wl.005 and sec.wl.006).

Regions also support the sec.wl.004 requirement for separation by Location (for example, country).

Operational security is handled through a combination of mechanisms including the above and security groups (sec.sys.002). Security groups limit the types of traffic that have access to instances. One or more security groups can be automatically assigned to an instance at launch. The rules associated with a security group control the incoming traffic. Any incoming

traffic not matched by a rule is denied access. The security group rules govern access through the setting of different parameters: traffic source, protocols and destination port on a VM. Errors in provisioning/managing OpenStack Security Groups can lead to non-functioning applications, and it can take a long time to identify faults and correct them. Thus, the use of tools for auto provisioning and continued inspection of security groups and network policies is required.

Given the rate of change in the workload development and deployment, and the cloud environment itself, sec.wl.003 requires that the workloads must be assessed during the CI/CD process as the images are created and then whenever they are deployed. In addition, the infrastructure must be configured for security as discussed elsewhere in this section including secure boot.

6.3.4.1 SR-IOV and DPDK Considerations

The SR-IOV agent only works with NoopFirewallDriver when Security Groups are enabled but can still use other firewall_driver for other Agents by updating their conf with the requested firewall driver. Please see SR-IOV Passthrough for Networking **Error! Reference source not found..**

Operators typically do not implement Security Groups when using SR-IOV or DPDK networking technologies.

6.3.5 Image Security

Images from untrusted sources must not be used (sec.img.001). Valuable guidance on trusted image creation process and image signature verification is provided in the “Trusted Images” section of the OpenStack Security Guide [Error! Reference source not found.](#) The OpenStack Security Guide includes reference to the “OpenStack Virtual Machine Image Guide” **Error! Reference source not found.** that describes how to obtain, create, and modify OpenStack compatible virtual machine images.

Images to be ingested, including signed images from trusted sources, need to be verified prior to ingestion into the Image Service (Glance) (sec.gen.009). The operator will need toolsets for scanning images, including for virus and malware detection (sec.img.002). Adding Signed Images to the Image Service (Glance) is specified in OpenStack Operations Guide **Error! Reference source not found..** Image signing and verification protects image integrity and authenticity by enabling deployers to sign images and save the signatures and public key certificates as image properties. The creation of signature per individual artefact in the VNF package is required by ETSI GS NFV-SOL004 0.

The chain of trust requires that all images are verified again in the Compute service (Nova) prior to use. Integrity verification at the time of instantiation is required by ETSI GS NFV-SEC021 0.

Images must be also updated to benefit from the latest security patches (sec.gen.008, sec.img.007).

6.3.6 Security LCM

Cloud Infrastructure LCM encompasses provisioning, deployment, configuration and management (resources scaling, services upgrades, etc.) as described in [Section 7](#). These

operations must be securely performed in order to keep the infrastructure safe and operational (sec.lcm.003).

6.3.6.1 Provisioning/Deployment

Regarding the provisioning of servers, switches, routers and networking, tools must be used to automate the provisioning eliminating human error. For Infrastructure hardware resources, a set of recommendations is detailed in Section 7.2.1 to automate and secure their provisioning (sec.lcm.001).

For OpenStack services and software components, deployment tools or components must be used to automate the deployment and avoid errors. The deployment tool is a sensitive component storing critical information (deployment scripts, credentials, etc.). The following rules must be applied:

1. The boot of the server or the VM hosting the deployment tool must be protected
2. Integrity of the deployment images must be checked, before starting deployment
3. Deployment must be done through dedicated network (e.g., VLAN)
4. When the deployment is finished, the deployment tool must be turned-off, if the tool is only dedicated to deployment. Otherwise, any access to the deployment tool must be restricted. Strict access permissions must be set on OpenStack configuration files.

6.3.6.2 Configuration and management

Configuration operations must be tracked (sec.gen.015, sec.mon.006, sec.mon.007). Events such as system access attempts, actions with high privileges, modification of configuration, must be logged and exported on the fly to a non-local storage. The communication channel used for log collection must be protected for integrity and confidentiality, and the logs protected against unauthorised modification (sec.mon.004).

Per sec.sys.0016 and sec.lcm.002 requirements, management protocols limiting security risks must be used such as SNMPv3, SSH v2, ICMP, NTP, syslog and TLS. How to secure logging is described in the following section?

6.3.6.3 Platform backup

The storage for backup must be independent of storage offered to tenants.

6.3.6.4 Security upgrades

To defend against virus or other attacks, security patches must be installed for firmware, OS, Hypervisor and OpenStack services according to their criticality.

6.3.7 Monitoring and Security Audit

This intent of this section is to provide a key baseline and minimum requirements to implement logging that can meet the basic monitoring and security auditing needs. This should provide sufficient preliminary guidance but is not intended to provide a comprehensive solution. Regular review of security logs that record user access, as well as session (sec.mon.010) and network activity (sec.mon.012), is critical in preventing and detecting intrusions that could disrupt business operations. This monitoring process also allows administrators to retrace an intruder's activity and may help correct any damage caused by the intrusion (sec.mon.011).

The logs have to be continuously monitored and analysed with alerts created for anomalies (sec.lcm.005). The resources for logging, monitoring and alerting also need to be logged and monitored, and corrective actions taken so that they are never short of the needed resources (sec.mon.015).

6.3.7.1 Creating Logs

1. All resources to which access is controlled, including but not limited to applications and operating systems, must have the capability of generating security audit logs (sec.mon.001).
2. Logs must be generated for all components (e.g., Nova in OpenStack) that form the Cloud Infrastructure (sec.mon.001).
3. All security logging mechanisms must be active from system initialisation (sec.mon.018):
 - a) These mechanisms include any automatic routines necessary to maintain the activity records and clean-up programs to ensure the integrity of the security audit/logging systems.
4. Logs must be time synchronised (sec.mon.002).

6.3.7.2 What to Log / What NOT to Log

What to log

6.3.7.2.1

Where technically feasible the following system events must be recorded (sec.mon.005):

1. Successful and unsuccessful login attempts including:
 - a) Command line authentication (i.e., when initially getting token from keystone)
 - b) Horizon authentication
 - c) SSH authentication and sudo on the computes, controllers, network and storage nodes
2. Logoffs
3. Successful and unsuccessful changes to a privilege level (sec.lcm.012)
4. Successful and unsuccessful configuration changes
5. Successful and unsuccessful security policy changes
6. Starting and stopping of security logging
7. Creating, removing, or changing the inherent privilege level of users (sec.lcm.012)
8. Connections to a network listener of the resource
9. Starting and stopping of processes including attempts to start unauthorized processes
10. All command line activity performed by the following innate OS programs known to otherwise leave no evidence upon command completion including PowerShell on Windows systems (e.g., Servers, Desktops, and Laptops)
11. Where technically feasible, any other security events should be recorded

6.3.7.3 What NOT to log

Security audit logs must NOT contain:

1. Authentication credentials, even if encrypted (e.g., password) (sec.mon.019);

2. Keystone Token;
3. Proprietary or Sensitive Personal Information.

6.3.7.4 Where to Log

1. The logs must be stored in an external system (sec.mon.018), in a manner where the event can be linked to the resource on which it occurred.
2. Where technically feasible, events must be recorded on the device (e.g., VM, physical node, etc.) where the event occurs, if the external logging system is not available (sec.mon.021).
3. Security audit logs must be protected in transit and at rest (sec.mon.004).

6.3.7.5 Required Fields

The security audit log must contain at minimum the following fields (sec.mon.001) where applicable and technically feasible:

1. Event type
2. Date/time
3. Protocol
4. Service or program used for access
5. Success/failure
6. Login ID — Where the Login ID is defined on the system/application/authentication server; otherwise, the field should contain 'unknown', in order to protect authentication credentials accidentally entered at the Login ID prompt from appearing in the security audit log.
7. Source and destination IP Addresses and ports

6.3.7.6 Data Retention

1. Log files must be retained for 180 days, or the relevant regulator mandate, or your customer mandate, whichever is higher (sec.mon.020).
2. Implementation and monitoring: after 180 days or your mandated retention period, security audit logs must be destroyed.

6.3.7.7 Security Logs Time Synchronisation

The host and various system clocks must be synchronised with an authenticated time service/NTP server (sec.gen.007).

In any time, synchronisation, we need to specify the synchronisation interval and the tolerance where the latter specifies the permissible difference the local time can be out of synchronisation. Whenever the time synchronisation forces the local time to change or the use of another NTP server, the change details must be logged including time server source, time, date and time zones (sec.mon.003).

7 Operations and Life Cycle Management

7.1 Introduction

To create an Infrastructure as a Service (IaaS) cloud requires the provisioning and deployment of the underlying infrastructure (compute, networking, and storage) and

deployment, configuration and management of the necessary software on the infrastructure; in the process of deploying the software, configuration of the infrastructure may also need to be performed.

Instead of deploying the infrastructure components and services manually, the current best practice is to write *code* (Infrastructure as Code, IaC – please see NG126 Section 7.4.4 0) to define, provision, deploy, configure, and manage the IaaS cloud infrastructure and services. IaC tools allow the entire provisioning, configuration, and management processes to be automated. The desired state of the infrastructure and services is represented in a set of human readable, machine executable, and version-controlled files. With version control, it is easy to roll back to an older version and have access to the history of all committed changes.

The provisioning of the infrastructure is typically performed by provisioning tools while the deployment of the software and the configuration of the software, and where needed the infrastructure, falls in the domain of configuration management tools. A single tool may support both provisioning and configuration management.

Operators may choose certain paradigms with respect to how they provision and configure their IaaS cloud. These paradigms will drive the selection of the provisioning and configuration tools. In this section we will discuss the capabilities of provisioning and configuration management systems; some open-source tools may be mentioned but their capabilities are beyond the scope of this section.

7.1.1 Procedural versus Declarative code

The procedural style IaC tools require code that specifies how to achieve the desired state. Whilst the declarative style IaC tools require code that specifies the desired state (what not how). The major difference between the two styles emerges when changes to the desired state are required. In the procedural style, the change is coded in terms of the difference between the desired and current states while in the declarative style the new desired state is specified. In the procedural style, since the state difference has to be coded, a new code file has to be created for each change; in the declarative style, the existing code file is updated with the new state information. In the declarative style, knowledge of the current state is not required. In the procedural style, knowledge of the current state has to be manually figured by tracing the created code files and the order in which they were applied.

7.1.2 Mutable versus Immutable infrastructure

In the mutable infrastructure paradigm, software updates are made in place. Over time this can lead to configuration drift where each server becomes slightly different from other servers. In the immutable infrastructure paradigm, new servers are deployed with the new software version and then the old servers are undeployed.

7.2 Cloud Infrastructure and VIM configuration management

Section 9 “Configuration and Lifecycle Management” of the Reference Model 0 defines the functions of Configuration and Life Cycle Management (LCM). To operate and manage a scalable cloud, that minimizes operational costs, requires tools that incorporate systems for automated provisioning and deployment, and managing configurations that ensures the correctness and integrity of the deployed and configured systems.

7.2.1 Provisioning

This section deals with automated provisioning of the Cloud Infrastructure; for example, provisioning the servers, switches, routers, networking (e.g., subnets, routing tables, load balancers, etc.), databases and all required operating systems (Servers, switches, etc.).

The following are the minimum tasks that need to be performed by automation:

1. **Pre-boot configuration** such as BIOS/RAID/IPMI settings: Hardware manufacturers typically have their proprietary interface for these tasks but standards such as Redfish are being increasingly utilised. Consider using tooling to ensure consistency across all infrastructure components.
2. **Bootloader installation** of base Network Operating System (NOS) on networking equipment or the Operating System (OS) should be performed using PXE; again, consider tooling to ensure consistency across all infrastructure components.

Configuration and subsequent software installation is then handed over to a configuration management tool or life cycle manager.

1. OpenStack TripleO documentation **Error! Reference source not found.**, and similar documentation from OpenStack vendors, delves into great detail on the provisioning of servers (bare metal), deploying and configuring OpenStack services.
2. Section 6 of the Reference Implementation **Error! Reference source not found.** a set of Installer requirements are specified with a couple of Installers (such as Airship and Triple-O) are described in section 8.5 of the Reference Implementation **Error! Reference source not found.** It should be noted that the installers chosen in order to automate deployment depend on the cloud provider.
3. Systems such as Airship **Error! Reference source not found.** are not only provisioning tools but also a configuration management system. For example, Airship **Error! Reference source not found.** specifies how to provision and deploy the IaaS, and on how to update configuration including OpenStack services.
4. For Airship, section 8.5.1.1 of the Reference Implementation **Error! Reference source not found.** specifies the required descriptor files and section 8.5.1.2 of the Reference Implementation **Error! Reference source not found.** describes the steps to provision the OpenStack based IaaS.

7.2.2 Configuration Management

The configuration management system ensures the correctness and integrity of the deployed and configured systems. The tools provide the assurance that the expected software is running with the expected configurations on correctly configured nodes that continue to be configured correctly.

Configuration Management (CM) is composed of the following activities:

1. **Desired (Target) State:** a version of the software and hardware and their configurations. Depending upon the configuration management system these configurations are specified in cookbooks, playbooks, manifests, etc. The configuration specifications in these artefacts are used to configure the different types of nodes, BIOS, operating systems, hypervisor, and OpenStack services (through settings within their config files such as nova.conf, etc.).

2. Current State: the current configuration of software and hardware as provided by monitoring systems.
3. State variance mitigation: The CM system, on discovering a variance between the desired and current states, acts to drive the state to the desired state. Each CM system accomplishes the task in different ways.

7.2.3 Cloud Infrastructure and VIM Maintenance

Cloud Infrastructure and VIM Maintenance activities can be classified as

7. Deployment of additional infrastructure components (or removal of infrastructure components)
8. Cloud Infrastructure configuration changes
9. VIM configuration changes
10. Version changes (upgrade) of Cloud Infrastructure software (for example, Host Operating System, Hypervisor, etc.)
11. Version changes of VIM Software (or component services)

Deployment (or removal) of infrastructure components

In declarative tools, the code with the specified desired state (for example, number of compute servers) is modified to the new desired state. The IaC tool then ensures that the desired state is achieved. In procedural tools, the step-by-step code to deploy (remove) infrastructure components needs to be specified. Existing code can be cloned, and appropriate changes made to get to the desired state.

Configuration and Version Changes

Configuration and Version Changes are made in a similar fashion to the “Deployment of infrastructure components” except that the IaC tools used maybe different.

7.3 Logging, Monitoring and Analytics

1. Logging
2. Monitoring
3. Alerting
4. Logging, Monitoring, and Analytics (LMA) Framework

7.3.1 Logging

A log, in the context of computing, is the automatically produced and time-stamped documentation of events relevant to a particular system. All software, including operating systems, middleware and applications produce log files. Enterprises and vendors may have custom monitoring and logging solutions. The logging and monitoring systems capture events and data of interest to the Cloud Infrastructure and workloads so that appropriate actions can be taken. For example,

1. Operating systems and web servers maintain an access log of all access requests, session details and file access.
2. Databases maintain a transaction log of all transactions executed including any added, changed, and deleted data.

3. Audit logs record chronological documentation of any activities that may have affected a particular operation or event. Data typically includes resources accessed, destination and source addresses, and a timestamp and login information for the person who accessed the resources.

Some of the data is to support the metrics collection specified in Section 4 “Infrastructure Capabilities, Metrics and Catalogue” of the Reference Model 0.

Logs have multiple operational uses including for:

1. Regulatory Compliance and Security Information and Event Management (SIEM) featuring the automated gathering, analysis and correlation of log data across all systems and devices across an operator to provide real-time analysis, event prioritization, reporting, notification and alerting
2. Monitoring across systems in real-time to detect particular log events, patterns, anomalies or inactivity to gauge system and application health
3. Identify system and application performance and configuration issues
4. Root cause analysis for system and application failures and errors
5. Ensuring that operational objectives and SLAs are met

7.3.2 Monitoring

Monitoring is the process of collecting, aggregating, and analysing values that improve awareness of the components’ characteristics and behaviour. The data from various parts of the environment are collected into a monitoring system that is responsible for storage, aggregation, visualization, and initiating automated responses when the values meet specific threshold.

Monitoring systems fulfil many related functions. Their first responsibility is to accept and store incoming and historical data. While values representing the current point in time are useful, it is almost always more helpful to view those numbers in relation to past values to provide context around changes and trends.

7.3.3 Alerting

Alerting is the responsive component of a monitoring system that performs actions based on changes in metric values. Alert definitions are composed of two components: a metrics-based condition or threshold, and an action to perform when the values fall outside of the acceptable conditions.

While monitoring systems are incredibly useful for active interpretation and investigation, one of the primary benefits of a complete monitoring system is letting administrators disengage from the system. Alerts allow the specification of situations that make sense to actively manage, while relying on the passive monitoring of the software to watch for changing conditions.

7.3.4 Logging, Monitoring, and Analytics (LMA) Framework

In this section, a possible framework utilising Prometheus, Fluentd, Elasticsearch and Kibana is given as an example only.

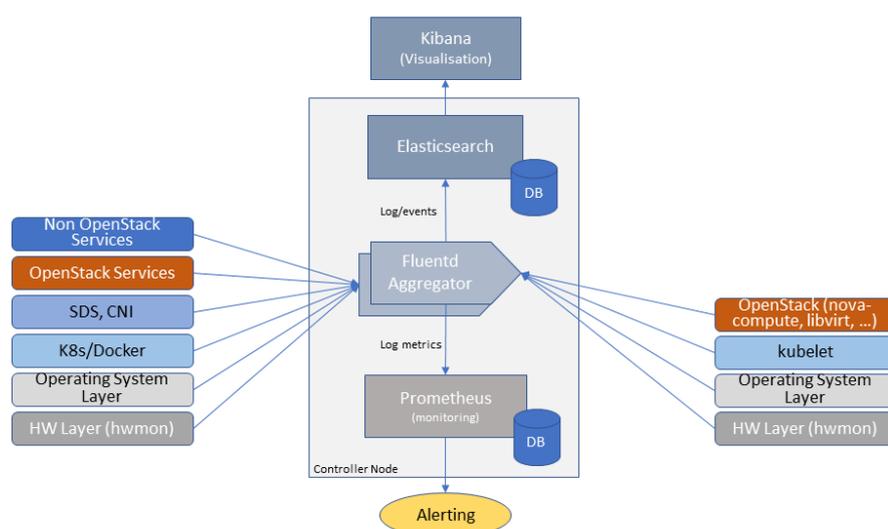

Figure 11 Monitoring and Logging Framework

The monitoring and logging framework (Error! Reference source not found.) leverages Prometheus as the monitoring engine and Fluentd for logging. In addition, the framework uses Elasticsearch to store and organize logs for easy access. Prometheus agents pull information from individual components on every host. Fluentd, an open-source data collector, unifies data collection and consumption for better use and understanding of data. Fluentd captures the access, application and system logs.

8 Gaps, Innovation, and Development

8.1 Introduction

The purpose of this section is to identify the gaps between what is required for automated deployment of VNFs on Cloud Infrastructure frameworks and the framework offered by OpenStack. Once gaps are identified, the next step will be to propose a plan to address these gaps. The most obvious way to address the gaps will be to propose a set of APIs in the upstream OpenStack community

8.2 The Gap

8.2.1 Autoscaling

With regards to resource autoscaling (req.gen.scl.01) it is recommended that the NFVO/VNFM manages the policy and triggers a scale-up or scale-down action based on application telemetry, event, AI, or ML etc. While the use of telemetry and alarming system can trigger a scaling operation based on resource utilisation, without application context this may not provide the granularity or reaction time required by the application. It is therefore suggested that an OpenStack scaling operation is called using an appropriate autoscaling web-hook by the NFVO/VNFM.

For more information on auto-scaling with Heat please see **Error! Reference source not found.** Please note that the OpenStack Senlin service is still under development with major architectural changes made in the OpenStack Ussuri release. It might be possible for the next version of this RA to recommend Senlin for auto-scaling.

Please note that physical compute node autoscaling is out of scope.

8.3 OpenStack Release Gaps

Section contains the API versions and key differences between the chosen baseline version (Train), the current version for RI (Ocata) and the potential future version for RI (Stein). The table below gives only an overview of the differences. For detailed changes, please check the OpenStack Releases **Error! Reference source not found.** document.

Service Name	OpenStack (Ocata) (RI version)	OpenStack (Train) (baseline)	OpenStack (Stein) (potential future RI version)
Keystone	3.8	3.13 <ul style="list-style-type: none"> - Support for delegating fine-grained privileges. - Supports the admin, member, and reader default roles across system-scope, domain-scope, and project-scope. - Different role API uses new default policies that make it more accessible to end users and administrators in a secure way. 	3.12 <ul style="list-style-type: none"> - Support for project tags, application credential, domain level resource limits, JSON Web Tokens. - Introduced system scoped roles - Introduced new role 'reader' along with 'member' and 'admin'
Glance	2.5	2.9 <ul style="list-style-type: none"> - Support for compressed container formats. - Block Storage service always creates a new secret in Barbican when it uploads a volume as an image. 	2.7 <ul style="list-style-type: none"> - Version v1 is removed - Support for hidden images, interoperable image import using image data (glance-direct) or image URL(web-download), - Fixed OpenStack Security Note OSSN-0075 0 - Multi backend support to configure multiple stores
Cinder	3.27	3.59	3.59 <ul style="list-style-type: none"> - Support for multi attach and deferred deletion for RBD driver - Support for image signature verification when creating volume from image

Service Name	OpenStack (Ocata) (RI version)	OpenStack (Train) (baseline)	OpenStack (Stein) (potential future RI version)
Nova	2.42	2.79 - Support for servers with a NUMA topology, pinned CPUs and/or huge pages, and SR-IOV ports attached when using the libvirt compute driver. - Support for hardware-based encryption of guest memory to protect users against attackers or rogue administrators snooping on their workloads.	2.72 - Support for vGPUs - Support for volume type in server create API - Support to create servers with ports that have QoS minimum bandwidth rule - Security enhancements when using Glance signed images
Swift	1.0	1.0	1.0
Neutron	2.0	2.0 - Support for Smart NIC in ML2/OVS mechanism driver to bind the Neutron port for the baremetal host with Smart NIC. - Introduced support for a notifier that sends notifications on relevant resource events/changes to the OpenStack Baremetal service (ironic).	2.0
Orchestration	1.0	1.0	1.0
Placement		1.36	

Table 86 Main differences between OpenStack releases

Additionally, Stein release also provides an upgrade check before actually upgrading any of the services. See more details on upgrade-check **Error! Reference source not found..**

Annex A Document Management

A.1 Document History

Version	Approval Date	Brief Description of Change	Approval Authority	Editor / Company
1.0	03/11/2021	Document First Version	ISAG	Walter Kozlowski/Telstra

Type	Description
Document Owner	NG
Editor / Company	Walter Kozlowski/Telstra

A.2 Other Information

It is our intention to provide a quality product for your use. If you find any errors or omissions, please contact us with your comments. You may notify us at JSendin@gsma.com

Your comments or suggestions & questions are always welcome.
